THE AMERICAN ARCHITECT AND BUILDING NEWS

VOL. LXXV SATURDAY, JANUARY 4, 1902 No. 1358

CONTENTS

SUMMARY: —
The International Edition in Quarterly Form. — The new Building Commissioner of New York asks Aid of the Architects. — Death of Edw. Onslow Ford, Sculptor. — The Fire-loss for 1901. — The Direct Employment of Labor by Owners. — The Real Value and Usefulness of the Contractor. — The Attitude of the German Emperor towards certain Artists and their Work. — The Value of Forests as Producers of Oxygen. — Threatened Rise in the Price of Window-glass. 1
NOTES ON IRON AND STEEL CONSTRUCTION. — I. 3
THE CATHEDRALS ONE WILL NEVER SEE. 5
BOOKS AND PAPERS. 6
ILLUSTRATIONS: —
New Theatre, Corner of Tremont St. and Van Rensselaer Place, Boston, Mass. — Section of same Building — Cathedrals that One will never see: — Laon; Strasbourg; Rheims; Amiens; Chartres; Paris; Beauvais.
Cancello della Villa Massimi, in Via Merulana, Rome, Italy.
Additional: The Atlantic Building, Wall and William Sts., New York, N. Y. — Detail of the Same. — Detail of Central Fountain: Villa Lante, Bagnaia, Italy. — Drummond Castle, from the South. — Deciduous Cypress: Villa Doria-Pamphili, Rome, Italy. — Gateway: Hampton Court Palace; Gateway: Syon House, Middlesex, Eng. 7
NOTES AND CLIPPINGS. 7

TOO late in the season to allow us to perfect our plans and make announcement earlier, we determined to make a change in the manner and method of publishing our International edition, and we now give notice that the change impends and will have effect in the second quarter of the year. The change consists simply in gathering the extra illustrations which constitute the International edition into four quarterly issues in place of their being, as now, scattered through thirteen weekly issues. The result will be that the subscriber to the International edition will receive each week a copy of the Regular edition and with each quarter a quarterly volume in which will be collected the gelatine and other International plates. That is, a subscriber will receive exactly what he now receives, but it will reach him in what, we believe, will be a more acceptable and agreeable form. Amongst other advantages incident to this condensation of matter is the fact that it will enable us to publish in the same issue all the plates in illustration of a given building, instead of being forced to let them dribble out, a few at a time, in four or five different weekly issues, as in the past.

MR. P. M. STEWART, the new Building Commissioner for the Borough of Manhattan, has had an excellent idea, although it is not, as yet, very evident how he is to carry it out. Realizing the superiority of foreign cities to New York in imposing and beautiful general effects, he has formally invited "the American Society of Architects," which, we suppose, means the New York Chapter of the Institute, to coöperate with his Department "in securing, so far as is practicable, more artistic effects in the city's architecture." The "American Society of Architects" will, we are sure, be very happy to lend all the aid in its power to this excellent scheme, and the public will bless both it and Mr. Stewart for whatever they may be able to accomplish in the desired direction, but it is not so clear how they are likely to be able to accomplish anything. Under the present New York building-laws, any man can, practically, construct anything he likes on his land, provided it is reasonably incombustible; and regulations like those in force in Europe, where Governments exercise their police power in regulating the heights of cornices and string-courses, while admirable in their effect on the artistic beauty of cities, would hardly be suited to our notions of individual liberty.

IT should, however, be remembered that the best effects of city architecture in Europe are not the result of police regulation, but of voluntary agreement. The Rue de Rivoli, in Paris, for example, which excites the admiration of all foreigners by the continuous arcading of the sidewalk, and its long, level lines of cornices, string-courses and balconies, was formed by the municipality, which, desirous of widening the narrow, dirty passageway, bordering the grounds of the Tuileries and the Louvre, acquired the lots facing on these passageways; and, after laying out a broad street, resold what was left of the lots, facing on the street, subject to the condition that all structures erected on these lots should have the first story uniformly arcaded, and should have the string-courses and main cornices at fixed levels. Although this transaction took place nearly a hundred years ago, the street, thanks to the foresight of those who planned it, is as attractive as ever. Around the Rond-Point de l'Étoile, which dates from the same period, and was laid out in the same way, the regulations are even more strict, and the uniformity extends even to the decorations of the fronts. In many cases in this country it would be possible to apply similar restrictions, and the city of Boston, for example, has lost a great opportunity to control the constructions on the lots fronting on its beautiful park, where, in consideration of the privilege of access from the park avenues, it has imposed only a few meagre regulations where it might have insisted on its own terms, to the great advantage of the lot-owners, as well as of the public.

THE world has lost a brilliant artist in the sculptor, Onslow Ford, who died in London a few days ago, at the age of forty-nine. Ford was in some respects the most remarkable sculptor of his time. Without the obtrusive eccentricity of some of the more original French artists, he was independent and imaginative to a degree which is rare among sculptors anywhere, and particularly so in England. Most of his artistic training was obtained abroad, and it is not impossible that his peculiar freedom of thought may have been, in part, the result of his varied experience and study. He belonged to a poor family, and, when only a boy of seventeen, he was taken from London to Dunkirk. Here he pursued the artistic studies for which he had already shown an aptitude under the direction of an old Frenchman. Later, he entered the School of Fine Arts in Antwerp, and studied drawing and painting there for nearly two years. From Antwerp circumstances took him to Munich, where he was led to turn his attention from painting to sculpture. His studies were interrupted by the necessity of returning to London for a time, but he afterwards went back to Munich to complete them. Returning again to England, he found employment in portraiture, and it was some time before an opportunity was afforded him for a work of real imagination. The first, perhaps, of these was a statue of General Gordon, which he was commissioned to execute for the city of Birmingham. Instead of presenting the eccentric hero on horseback, with the conventional cloak over his shoulder, he mounted him on a camel, contrasting his simple uniform with the embroidered and fringed trappings of the animal. This work brought him fame, and he soon had plenty of commissions. One of his last works was a figure of Shelley, for the University of Oxford, which shows the poet as he lay dead on the beach of the Gulf of Spezia, after his body was dragged from the water by his friends.

THE total of fire-losses for 1901 will amount, it is said, to more than one hundred and sixty million dollars in the United States and Canada, and we are treated to the usual rumors that "property-owners are to be forced to lessen the fire-hazard," and so on, which mark the close of the insurance year. There is no doubt that the fire-loss, to which must be added, probably, a hundred millions more for cost of maintaining insurance companies and fire protection, is too large. As we have before suggested, the money spent by the people of the United States every year in making bonfires of their goods, and trying, in vain, to put them out, would just about keep the entire population supplied with boots and shoes. Now, the idea of free boots and shoes perpetually for everybody is quite sufficient to make the fathers and mothers of families prick up their ears, and there is no danger that a real remedy for the evils of fire would not attract public attention. The trouble is that the underwriters, who could easily carry out any measures that they might agree upon, content themselves mainly with grumbling and threatening. Not long ago, according to the New York *Evening Post*, the manager of a property insured for several hundred thousand dollars, after reading, apparently, some of the eloquent speeches at an underwriters' banquet, was touched in his conscience, and inquired into the cost of proper

Copyright, 1901, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

protection against fire for the property which he had at risk. He found that the expense would be more than the amount of his present premiums for several years, and, like a conscientious man, he abandoned the project, feeling that he could not honestly sacrifice the interests of the owners of the property to a private fancy. We have ourselves had the same experience more than once, and until it is made for the interest of owners to use methods of protection against fire, it is very certain that few of them will do so.

THE English newspapers are being supplied, apparently by industrious "champions of labor," with a good deal of literature on the subject of the abolition of contractors, and the substitution of the system of the "direct employment of labor" by owners. Architects who have seen something of the "direct employment of labor" by people rich enough, and inexperienced enough, to be easy victims, will not be surprised that the suggestion should be received with cries of joy by the radical "friends of the toilers," but the other side has begun to take part in the discussion, and interesting facts, for the time, replace theories and predictions. One contractor, Mr. Wallis, writes an admirable letter to the *Builder*, asking why the experience of the contractor should not be of as much value in the business of construction as in any other; and refers to the costly experiment made by the London County Council, which was deluded into the notion that it could save twenty-five per cent of the cost of municipal work by being its own contractor, and, instead of that, after a series of disgraceful scandals, considered itself fortunate in being able to get work poorly and inefficiently done for a sum not very much greater than the cost of having it rapidly and efficiently executed by contract.

MR. WALLIS mentions some instances from his own experience of the result of encouraging rich and unsuspecting owners to employ labor "directly," either in building or engineering operations, which will not surprise architects. In one case, he saw five men and an overseer engaged, at good wages, in fishing an empty oil-barrel out of the water into which it had fallen; and in a fitting-shop he saw twenty-five men, also at good wages, employed in standing still, watching the two remaining men who alone made any pretence of doing any work. As to the influence of trades-unions on the efficiency of labor, about which there is so much dispute, he observes that men in places where there are no unions do, on an average, twice as much work in a day as in cities, where the unions rule the workmen.

WE imagine that American architects could add something to the illustrations of the difference in results between the "direct employment of labor" and the entrusting of the work to be done to a good contractor. We do not dare to say how many old packs of playing-cards we have found concealed near where some "labor" had been "directly employed" for several weeks by a wealthy proprietor, or how many empty whiskey-bottles were discovered under similar circumstances in another case. Of course, much work can only be done, or can be done most cheaply, by the day, and with an honest contractor to look after the men, at a reasonable compensation, there is no disadvantage in the system; but the time when all workmen can be trusted to labor faithfully and intelligently for an employer who has plenty of money, and does not have leisure to look after them, has not yet come, and will not come until politicians and college professors cease to hold up employers as "greedy monopolists," who have "seized upon the means of existence," by "exploiting the toilers," and whom it is desirable, in the interest of abstract justice, for the "toilers" to plunder in their turn whenever they get a chance.

THE Emperor of Germany has been unfortunate in incurring the hostility of certain artists who were not treated by him with the consideration which they thought they deserved, but he seems, notwithstanding their criticisms, to have very clear and excellent ideas in regard to art; and, in a recent speech, delivered at a dinner given in the palace to the artists of the Sieges-Allée, he gave good reasons for the favoritism with which he has been so much reproached. Concerning the present tendency of art to advertise itself by newspaper clamor, by the imitation of fashionable masters, and by a search for startling effects, he said, with justice, that the best way to counteract this degrading movement was for those in a position to command to seek out artists of great talent, and attach them to their courts, giving them liberty and opportunity to work out, under the protection of their patron, the inspiration of their hearts. The Emperor, in support of this theory, said that it was in this way that the great schools of art of the Middle Ages and the Italian Renaissance were formed, and, although the complete accuracy of this statement is, as a matter of history, doubtful, there is, at least, enough truth in it to confirm his view that in all ages, and now more than ever, an atmosphere of security and sympathy is essential to artistic development. Thus encouraged, the Emperor believes, with William Morris, that art has a great work to perform, particularly among those to whom fortune has denied wealth and leisure. As he well says, the Germans have risen to their present supremacy through their constancy to the great ideals which they have set before them, and it is the mission of art to elevate and comfort the poorer people by placing before them ideals of beauty, purity and love. It was William Morris's theory, founded on long experience, that a poor man whose æsthetic faculty had been awakened soon found a pleasure in the sunshine on the whitewashed walls of his little cottage, and the varying figures of his children, at play in the dark interior, that he would not exchange for the delights of a palace; and the most important, as well as the most neglected, principle of social science is, perhaps, that the key to the abolition of class distinctions, of the envy of the poor toward the rich, and the arrogance of the rich toward the poor, is to be found in art, which no class can monopolize, and which draws all, rich and poor, together by the purest and strongest sympathy. To be effective as a social force, however, the art must be good, that is, inspired with true feeling, and expressed simply and without affectation. If it is insincere or theatrical, it will fail to excite sympathy; and if its inspiration is bad, it will be an instrument of evil, instead of good. The Emperor said that "art which represents misery more hideous than it is sins against the people," and the point that the value of art lies in its power to keep before the world the ideals which it is the mission of civilization to cultivate should, particularly in these days of impressionism, of Sargent, Raffaelli and the other purveyors of soulless horrors, never be lost sight of.

FORESTRY Associations will do well to note a recent study, by Sir William Thomson, of the sources of oxygen in the earth's atmosphere. According to this, as reported in the newspapers, the original atmosphere of the earth consisted only of carbonic acid and nitrogen, and it was not until plants began to grow that oxygen, formed by the decomposition of carbonic acid in the leaves of the plant, by the influence of light, began to be mixed with the air. As time went on, and vegetation increased, the proportion of oxygen in the atmosphere increased also, until the mixture became fitted to support animal life, first in the lower grades, and, later, in a higher development. When man arrived, or was developed, the proportion of oxygen had reached its maximum, and he has, since then, expended a large portion of his energy, not only in consuming the oxygen that he found ready for him, but in cutting himself off from future supplies by destroying the vegetation which produces it. Since the discovery of coal, his resources for this sort of slow suicide have greatly increased, for every ton of coal, in burning, destroys about three tons of oxygen; and Professor Thomson observes that, ages before the exhaustion of the coal-supply, against which economists warn us, the oxygen supply will be so reduced that the air will be irrespirable. The obvious method of postponing this evil day is to add to the oxygen supply by increasing vegetation, and every one who makes a tree grow where one never grew before is not only helping to preserve the fertility and salubrity of the surrounding country, but is doing something to prolong the existence of the race on earth.

IT will interest contractors to learn from the New York *Evening Post* that "ruinous competition" has cut down the price of window-glass to such a point as to force "many dealers to conduct their business temporarily at a loss." To meet this sad condition of affairs, a "rise in price" is under consideration, to take effect early in 1902. We know of a good many contractors who would like to have the names and addresses of the dealers who sell window-glass "at a loss," and whose impression has been for a long time that the enormous prices asked for such glass were established by a monopoly which, under the shadow of a tariff-tax practically prohibitory, was making immense profits at their expense.

NOTES ON IRON AND STEEL CONSTRUCTION. — I.

ARCHITECTURE, in the completest and fullest sense of the day, embodies probably a more varied knowledge of the industrial arts and sciences than any other single profession. The man who follows architecture thoroughly and with distinction must necessarily not only be an economist, but must be, as well, an artist and a constructor. This last qualification, far from being the least, is of the utmost importance, an importance which, unfortunately, was not recognized a few years back, but which, from the very nature of things, must find its place to-day in the modern buildings of the large cities or towns.

How vastly more the term "constructor" means now than it did three or four decades ago; for to-day it is not sufficient to know somewhat of the rule-of-thumb methods of figuring the thickness of walls, the size of a joist or the construction of a king or queen post truss, having enough material in its construction to build a highway bridge and not enough strength in its connections to realize one-twentieth of the strength of its members. The constructor of modern buildings must be well versed in the strength of materials; he must know the mechanics of the beam or girder, and be well versed in the analysis of stresses in framed structures, as well as the shop-practice employed in their manufacture; he must, too, know all about the stability of arches and retaining-walls, together with the processes employed in deep excavation through plastic and unstable soils, and the construction of heavy foundations upon such soils, when required to support a great superimposed load.

It is the purpose of these articles, however, to deal entirely with that modern innovation, "steel-construction," and with the end in view of giving reliable and working data upon the subject succinctly and successively treated, the following is presented: —

The size of the beams and the sections of the columns, together with the dimensions of the members making up any structure framed and assembled, composing the framework of a modern building, are based upon data which must be assumed. The designer, in working from such uncertain data, can at best produce a building only approximately economical in its construction. The two uncertain factors making up the original assumption, and which fix the dimensions of the structural members in any building, are the dead and the live loads. The dead load is considered to include the weight of everything entering into the construction of the building, while the live load may safely be said to include all loads and forces external and independent of the building, and when classified in this manner embraces the wind load, either in its horizontal action against the side of a building, or in its normal action upon a roof, and it may also include under its heading the snow-load. When the live load is especially referred to in the design of the floor-construction, it is considered as representing the weight of people, merchandise, furniture, fixtures and machinery.

In calculating the dead load in a structure the design of the construction must first be decided upon, and since accuracy in this respect is impossible on account of the fact that the sizes of the elements are as yet undetermined, the dead load should always be checked carefully after the plans and sections of the building are well under way, and if the beams, columns, or trusses are found to be light, the rolled sections composing them should be increased in thickness until adequate cross-sections have been obtained. Correct assumptions and accuracy in the determination of the dead load are of the utmost importance, for the design and successful proportioning of the foundation footings depend mainly upon the data obtained from these calculations.

While the materials entering into the construction of the modern building are many, the architectural-engineer need only bear in mind the most important, more especially those which enter into wall, floor or roof construction. The weight of these materials should be ascertained carefully and not too much dependence placed upon data more or less general in its character. The following weights of the principal materials used in building-construction given in pounds per unit of surface or volume, depending upon which is the most useful in the calculations, have been compiled from reliable sources and are generally accepted as correct by practising engineers: —

WEIGHT OF COMMERCIAL STRUCTURAL TIMBER IN POUNDS PER BOARD FOOT.

Pine (southern yellow long-leaf)	3¼
Pine (white)	2
Pine (Oregon)	2¾
Spruce	2½
Hemlock	2
Maple	4
Chestnut	3½
Oak (live)	4¼
Oak (white)	4

WEIGHT OF METALS USED IN BUILDING-CONSTRUCTION.

	Pounds per cubic inch.	Pounds per cubic foot.
Structural steel	.283	490
Cast-iron	.260	450
Wrought-iron	.277	480
Copper (cast)	.319	552
Lead (commercial cast)	.412	712
Zinc	.253	438
Brass	.302	523
Bronze	.319	552

WEIGHTS OF MASONRY MATERIALS IN POUNDS PER CUBIC FOOT.

Asphalt, pavement composition	130
Bluestone	160
Brick, best pressed	135 to 150
Brick, common hard	110 " 125
Brickwork, pressed-brick	112 " 140
Brickwork, ordinary	110 " 112
Cement, Louisville	50
Cement, Portland	80 to 100
Cement, Rosendale	56 " 60
Clay, dry, loose	63
Concrete	120 to 140
Earth, dry, loose	72 " 80
Earth, dry, moderately rammed	90 " 100
Feldspar	166
Gneiss, common	168
Gneiss, hornblendic	175
Granite	170
Gravel	117 to 125
Hornblende, black	200 " 220
Lime, quick	95
Lime, quick, loose	53 to 59
Limestone	170
Loam, soft	110
Marble	164
Masonry, granite or limestone	165
Masonry, granite or limestone, rubble	154
Masonry, granite or limestone, dry rubble	138
Masonry, granite or limestone, rough mortar rubble	150
Masonry, granite or limestone, rough dry rubble	125
Masonry, sandstone	145
Pitch	75
Plaster-of-Paris	142
Quartz, common	165
Sand, pure quartz, dry, loose	90 to 160
Sand, perfectly wet	118 " 129
Sandstone, building dry	144 " 151
Shale, red or black	162
Slate	160 to 180
Soapstone, or steolite	170
Terra-cotta	110
Terra-cotta, masonry work	112
Tile	110 to 120
Traprock, quarried and piled	107
Traprock, compact	187

WEIGHT OF ROOF AND CEILING COVERINGS IN POUNDS PER SQUARE FOOT.

Corrugated-iron, No. 26 to No. 18, no sheathing	1 to 3
Corrugated-iron, No. 26 to No. 18, with 1″ hemlock-sheathing	3 " 5
Felt and asphalt, without sheathing	2
Felt and asphalt, with 1″ hemlock-sheathing	4
Felt and gravel, without sheathing	8 to 10
Felt and gravel, with 1″ hemlock-sheathing	10 " 12
Slate on laths, $\frac{3}{16}$″ to $\frac{1}{4}$″	7½ " 11½
Slate on sheathing $\frac{3}{16}$″ to $\frac{1}{4}$″	9 " 11
Copper, without sheathing	1 " 1½
Tinplate	1 " 1½
Shingles with laths	2¼
Skylight, glass $\frac{3}{16}$″ to $\frac{1}{2}$″, including frame	4 to 10
Lath and plaster ceiling	8 " 10
Tile, flat	12 " 15
Tile, corrugated	8 " 10
Tile on 3″ fireproof blocks	30 " 35

In making the necessary calculation for the dead load to be combined with the live, and to be used in determining the sizes of beams and columns, the general design of the floor-construction must be thoroughly studied and decided definitely. It is then a simple matter to make scale-drawings of the several sections of floor-construction between beams and from these calculate the weight of the construction per lineal foot of beam or per square foot of floor-area. It is always well in determining the unit dead load on a floor to disregard the usual tables

giving the weight of the different systems of flooring, and to make one's own calculations for each particular case in hand. By using actual weight and accurate calculations in each specific case, data regarding the requirements of the beams and girders entering into the floor-construction may often be determined that will lead to the adoption of considerably lighter beams and girders, and hence a material saving in cost will be instituted. In the preliminary consideration of a building the time cannot always be spared in order to take up the thorough study of these details, and therefore it is necessary to have at our command data which will give approximately the weight of such floor-constructions as are in everyday use. The following tables are as nearly correct as such generalizing under the several items will admit: —

WEIGHT OF USUAL FLOOR-CONSTRUCTIONS IN POUNDS PER SQUARE FOOT.

Ordinary joist, wood floor, plaster ceiling	20
Heavy wooden girders, 3″ rough floor, 1″ finished floor	18
Brick arch, 4″ thick, concrete filling, 1″ finished floor: —	
8″ I-beam	75
9″ I-beam	80
10″ I-beam	90
12″ I-beam	100
15″ I-beam	120
Hollow brick flat arch, ordinary type: —	
8″ I-beam	70
9″ I-beam	75
10″ I-beam	80
12″ I-beam	90

The uncertain factor in figuring the dead load is the weight of the floor-beams, the sizes of which have as yet not been determined. Any rule which will give this information, even though it is only approximate, and far from accurate, is of value. There has been such a rule evolved, based on the condition that beams are designed upon the same limitations that are usually employed, and which will be given later. This rule applies to steel beams only and is as follows: —

$$W = \frac{L \times S^2}{1{,}000 \times d}$$

In which W equals the weight of the floor-beams in pounds per square foot of floor-area; L equals the combined live and dead loads in pounds per square foot of floor-area; S equals the span of the beam in feet, plus the length of the beam-bearing; 1,000 a constant, and d the depth of the beam in inches.

In order that the above may be clear, the following example may be interesting: —

Example. — The span of a beam supporting a floor-load of 150 pounds is 20 feet; what will be the weight of the beams per square foot of floor-area, provided 15-inch beams are used?

Solution. — From the problem, the values of the symbols in the formula are as follows: L 150; $S^2 = (20 + 1.5)^2$ or 462.25, 9 inches at either end being taken for the bearing of the beam at either end; $d =$ 15 inches. Then substituting in the formula we have

$$W = \frac{150 \times 462.25}{1{,}000 \times 15} = 4.62$$

While the dead load is at first only based on a series of assumptions, it is eventually accurately determined; not so, however, with the live load, which is probably never within 25 per cent of the load assumed. This load is so variable in amount that only an assumed load, which must be the maximum, can be taken. Since this maximum load is nearly always considerably in excess of the actual load, it is necessary to include in the structural members of a building considerably more material than is ordinarily required. It is, therefore, economy to keep the maximum live-load as low as possible after a careful analysis of the conditions obtaining in the particular building has been made. All original investigation along this line is therefore extremely valuable, and authentic data regarding the live-loads that obtain in existing buildings should be carefully scrutinized.

Many buildings at present erected are designed for excessive live loads, but as it is usually necessary to conform to certain building-laws, which are extremely general in their application and consequently inadequate, the designer cannot figure on the light loads which he knows will amply meet the requirements. The modern office-building, for instance, is hardly likely to fill any other function in the business world than it does, and statistics show that no office contains a greater load than 40 pounds per unit of floor-space, and that the average load is not one-half this amount; nevertheless, the limitations imposed by the several city ordinances are far in excess of this amount. It is well, undoubtedly, to be on the side of safety, but where heavy live loads are impossible, owing to the nature of the structure and means of intercommunication, it would seem that greater latitude should be given.

In buildings for public assembly there is hardly a necessity for a load of more than 80 pounds per square foot, which is the average weight of a densely-packed crowd of people, though in the case of a panic an unusual condition of loading may result, and a load of 120 pounds or more be attained. It would seem reasonable, however, to adopt the light load in figuring, especially in buildings where there are fixed seats, pews or benches, for on such a floor-area even the load of 80 pounds will not obtain except in the aisles. The necessity for a larger live-load than 40 pounds per square foot of floor-surface does not exist in dwelling-houses, except for the fact that on occasion they are subject to the same condition as an assembly hall or room; and then, too, there is no class of building situated in the midst of a city that more quickly outlives its original use than a dwelling-house; for these reasons a live load of 70 pounds should usually be considered. Such a live load is, however, not necessary in designing a country house, at least in all rooms and halls not used for assemblies, and 40 pounds will be adequate except for those wherein 70 pounds would be a better assumption and one sufficiently safe.

All other buildings, such as factories, warehouses, machine-shops and printing-plants, are designed for specific purposes; and they should be carefully designed to fulfil the conditions of loading which are reasonably likely to occur under actual working conditions. In fact, for this class of buildings it is entirely impossible to fix any general rules as to the amount of the live load to assume. One single floor of a plant may be subjected to twice the live load that would obtain on the other floors, and consequently should be proportioned for the additional burden. Then again, the vibration of moving machinery is an important factor which is often overlooked in the design of floor-construction; it is, nevertheless, a factor that should never be neglected in the consideration. The floors of printing-plants are especially liable to a vibratory movement, owing to the nature of the machinery, and in designing the floors of buildings erected for this purpose too much care cannot be exercised in order to secure stiff girders and beams, and broad bearings and rigid connections.

The live loads usually assumed for buildings built for many purposes and requirements are as follows: —

LIVE LOAD IN POUNDS PER SQUARE FOOT USUALLY ASSUMED IN BUILDINGS OF DIFFERENT CLASSES.

Country and suburban houses: —	
Sleeping-rooms, studies, etc	40
Halls, ball-rooms, dining-rooms, etc	70 to 80
City houses	70 " 80
Churches, theatres	80 " 120
Drill-halls, dancing-halls, etc	120 " 150
Manufacturing-plants	120 " 400
Machine-shops	150 " 450
Warehouses	150 " 500

When a careful analysis of the dead and live loads is not made in the preliminary study or the hasty design of a building, recourse is had to data which cover both, and the following table can be considered as conservative and accurate as such a general recapitulation can be: —

ENTIRE LOAD IN POUNDS PER SQUARE FOOT USUALLY ASSUMED IN THE DESIGN OF FLOORS FOR DIFFERENT PURPOSES.

Plank covering, lightest construction	100
Brick arches	150
Light-warehouse floors	200
Places of public assembly	200
Heavy warehouses	300 to 600
Shop-floors for light machinery	250
Shop-floors for heavy machinery	300 to 500

In the design of a modern steel structure all of the members must be proportioned for the full live load that they will be required to sustain; it is, however, not considered necessary practice or economical construction to proportion all the members in the structure for the maximum live load that the utmost possibilities of loading may necessitate. The floor-beams must always be proportioned for the full live load, for some of them are more than likely at one time or another to be fully loaded. That all of the floor-beams in a system of flooring depending

for its support upon a principal girder are likely to be loaded with the full live load at any particular time is highly improbable, and, consequently, good practice would seem to dictate that only 90, or possibly as low as 80, per cent of the maximum live load may be figured as coming upon the principal girders. The high office-buildings of modern construction contain many floors, supported by tiers upon tiers of columns, and as the sectional supporting-area required in any one floor must be carried to the foundation-footing through all of the intervening columns, it can readily be seen how important it is, for economical reasons, that the loads upon these principal supports should be reduced to the lowest possible amounts consistent with safety.

That all the floors of an office-building should be called upon to sustain the maximum live load all at the same time is not likely, even if with the present means of intercommunication and usual transaction of business it were possible, and so a certain reasonable reduction in the percentage of all the live load above that a tier of columns may be called upon to carry can certainly be made. This percentage of reduction is entirely a matter that lies within the individual designer's province in the construction of the particular building in hand, and no data or rules general in application will be of much practical value. In this connection the above data giving the amount of the live load and the percentage of increase of the same load from the floor above, of a thirteen-story building of the skeleton-construction type erected in Chicago, may be interesting as a sample of how much economy may be effected by the adoption of such assumptions : —

	Live load per square foot of floor-area.	Live load on columns from floors above.	Total live load on columns.
Roof	40		
Thirteenth floor	50	40	40
Twelfth floor	50	45	85
Eleventh floor	50	41	126
Tenth floor	50	35	161
Ninth floor	50	31	192
Eighth floor	50	25	217
Seventh floor	50	21	238
Sixth floor	50	15	253
Fifth floor	50	11	264
Fourth floor	50	5	269
Third floor	50	1	270
Second floor	50		270
First floor	125		270
Basement		50	320

M. M. Sloan.

[To be continued.]

THE CATHEDRALS ONE WILL NEVER SEE.

TWENTY years ago, after having chatted awhile about grotesque and symbolic sculpture, in that immense workshop in the Rue Condorcet, Viollet-le-Duc showed me some of his admirable drawings: bird's-eye views drawn with the hand of an expert and delicately tinted, studies and details of the most astounding precision; then, halting a few seconds before a superb drawing of the Cathedral of Paris, he cried, "Just think, there is not a single cathedral, not one, understand you, which has been finished as it was intended to be!"

This exclamation has very often occurred to my mind, and I ask myself if it would not be interesting to give in a few sketches, intentionally neglecting the details in order to simplify and aggrandize the appearance of the *ensemble*, I ask myself if it would not be amusing, perhaps even interesting, if not instructive, to give a sketchy presentation of the cathedrals which will never be seen!

And first, it must be said, cathedrals built as one operation are rare, and ought to be. It would, in fact, be necessary for this that the work should be carried on with incredible rapidity and with boundless resources, at those epochs where each style of architecture frankly had the better of earlier styles, where each century built according to that formula of art which was familiar to it.

I can better make understood by the detail of some church — the façade of the Cathedral at Rouen, for instance — this principle of the superposition of styles which prevailed up to the end of the eighteenth century. And in this connection, I must remark that in all the drawings [see Illustrations] the tinted surfaces show the edifice as it exists, while the additions, the portions projected or not executed, are merely indicated in line.

Now, regarding the tower of Saint Romain, a single glance will show through what phases it has, or might have, passed. In the first place, the primitive construction is of the twelfth or thirteenth century, showing a charming little staircase tourelle which most happily breaks in on the symmetry of one of the faces of the tower. Then, the upper platform, destroyed by a fire, was levelled, and they busied themselves with completing the tower. According to the plans of the early architect, the tower should have been crowned with a grand pyramid, flanked by four smaller pyramidions, in the style of that which finishes off the staircase turret. This cannot be doubted. But years passed, resources were lacking, and so we come to the fifteenth century. Then, the architect, Guillaume Pontifz, no longer hesitates; he crowns the ancient stories with a new one, beflowered, ornamented with balustrades, pinnacles, arcades and statues the richness of whose details frankly breaks with the masculine simplicity of the portions already built. And even then it is not done. It must be finished, it must be covered, in a word. Suggestions are asked for from different artists; for a time there is an idea of finishing the tower as a campanile. Finally, after long discussion, they adopt the form of a pavilion roofed in iron which is decorated with carvings and appliqué-work in metal. But, I suppose this roof to be destroyed at the commencement of the seventeenth or even eighteenth century. Never, never, would the architects of those times have reëstablished it, and we might have seen the tower of Saint Romain finished, as the last sketch shows, by an openwork campanile, in several stories retreating one above the other.

I give this as an example of the superposition of styles — especially in the matter of spires and towers — which so completely modifies the aspect of the *ensemble* of cathedrals, of which fact, moreover, there are numerous proofs, as at Chartres, Strasbourg, and so on.

Two cathedrals, particularly, which have escaped this superposition of styles must, nevertheless, be mentioned. For the completion of one — Cologne — architects of methodical mind, wise and conscientious, set themselves a task full of self-abnegation, since it continued purely and simply to completion an unfinished edifice. They worked according to the painstaking principles of the stone-mason who measures the ancient profiles, and cuts them with most scrupulous care from new blocks of white stone which can be substituted for the blocks of stone blackened by time, and which are then slipped into place as into a cell, without leaving a millimetre's play.

The choir of Cologne Cathedral, begun in 1248, was finished in 1322. The work was interrupted in the sixteenth century. Then, in the last century, from 1817 to 1880, work was carried on steadily, and to-day the Cathedral of Cologne, finished only a few years ago, Gothic from base to summit, rears towards the sky its two immense towers of openwork stone 156 metres high. But this veritable *tour de force* of unity of style, so energetically carried out, was possible only in our epoch, after the development of the science of archæology — a development which is one of the characteristics of the nineteenth century.

Earlier than this, such an achievement was impossible, and another cathedral — the Cathedral of Orleans — gives us an indisputable proof of this. In 1562, the inhabitants of Orleans saw their cathedral devastated; they wished to rebuild it. Up to this point, well enough. But, by an oddity not wholly free from obstinacy, instead of asking of the architects of the seventeenth and eighteenth centuries plans for a *new* structure, they demanded of these architects that, abandoning the formulas which were familiar to them, they should *reconstruct* the cathedral exactly, that is to say, should rear a Gothic structure. Now, at this time, not only the taste for Gothic building was not the fashion, but no one even knew how to draw a Gothic edifice with exactitude. This may appear extraordinary, but it is a fact. Let any one consult a number of the finest plates engraved in the last century, and he will see that the characteristic line of Gothic structure is wholly unknown to the most skilful draughtsmen, who always had a tendency to apply the formula of the pilaster and entablature of their own epoch to the structures of earlier centuries which they believed they were portraying.

So it is that the Cathedral of Orleans is the most ridiculous interpretation of Gothic which it is possible to dream of. The robust buttresses have been transformed into pilasters with columns at the angle; the pointed arches — and what arches! — rest on entablatures. The disproportioned arcades, the openwork cresting, like jig-sawed woodwork, and the tympana with their childish rose-windows make everybody laugh.

Would it not have been better, a hundred times better, as Victor Hugo has so well said, that "the great structures, like great mountains, should be the work of ages; that each wave of time should superpose its own alluvion, that each race should add its layer upon the monument, that each individual should add his own stone?"

Thus much said, a comparison of certain façades will show us what might be the change of aspect of some cathedrals if only we could see them finished. The Cathedral of Laon is one of the most beautiful buildings of the thirteenth century, and ought to have as many spires and towers as Rouen; the drawing of the façade indicates with clearness that the towers, with their openwork buttresses and silhouettes of animals detaching themselves against the sky in so decorative a manner, are not yet finished. A poverty-stricken balustrade now finishes the platform, while two pyramids with spirelets crowning the angle-buttresses — now decorated with oxen of huge dimensions — should have crowned with absolute symmetry this façade of so masculine a simplicity.

The Cathedral of Amiens, also, does not appear as it should. The richness of its façade is admirable. Less sumptuous than that at Rheims, but with a beauty of line perhaps at the same time more robust and more elegant, the façade should have for complement two towers, which, as we now perceive, must be dissimilar. To-day, the platforms above the balustrades are protected by little roofs, and conical or pyramidal roofs decorated with lead crown the staircase turrets. But if we suppose these two towers finished — either in the

fourteenth or fifteenth centuries — grafting upon the existing bases the confectionery-work carving of new stories, rendered still more delicate by contrast with the robust buttresses that flank the towers, these would have given to the Cathedral of Amiens an aspect of incomparable richness.

And no more is the Cathedral at Strasbourg finished, and the tower which is lacking was, nevertheless, very necessary. Doubtless, we have become habituated to the present silhouette. The "Münster," with its spiral staircase, 142 metres high, losing itself in the morning mist, gives to the façade a very characteristic silhouette; it is, nevertheless, true that there lacks a pendant to this fourteenth-century tower. This pendant, most likely to be built in the fifteenth and sixteenth centuries, would, in all probability, have been more elevated than the "Münster," for it is an almost constant law that each century always seeks to excel its predecessor, and, probably, this new spire would far have surpassed the spires of Cologne. But, unfortunately, it never did exist and never will exist!

If now we look at cathedrals in profile, those especially which ought to have several spires or towers, we shall be impressed with the change in silhouette of these great edifices. First I will speak of the superb drawings of Viollet-le-Duc. This eminent architect, in fact, made a drawing of the façade of the Cathedral of Paris and a bird's-eye view of the Cathedral at Rheims which give a marvellously exact idea of what the aspect of these two cathedrals should have been, but which we shall never see.

"If the façade of Notre Dame of Paris is very beautiful as it exists to-day," he often said, "we must, nevertheless, remember that everything had been so well prepared for the stone spires that we cannot but regret their absence. In the construction of the towers there is a force and strength which is not justifiable, since they carry nothing. Now, if these piers, so skilfully planted, if these grand bays terminated with masculine archivolts, if this structure, somewhat heavy for its crowning, could only be finished with spires, how elegant all would appear!"

All this is perfectly true, but it does not prevent, if on one fine day we should see scaffoldings set up and work begun on the building of the stone spires, that there should break out such a riot among certain alleged amateurs and archæologists that the audacious architect who should undertake such a work would be obliged to seek safety in quick flight. The public doesn't like to be disturbed in its habits. We saw this a few years ago when Falguière set up on the Arc de Triomphe his full-sized model, which set the grand silhouette of a quadriga against the light of a setting sun. The composition was pretty enough; some of the figures at the angles should have been altered — as was agreed by the sculptor himself. The model was left there to rot away slowly and make itself unpleasant, and, finally, to fall to pieces: so the Arc de Triomphe remains as it was, without crown, because the public was not accustomed to see it otherwise and, not liking to change its habits, disdainfully turned its back upon the artist's project.

For the real finishing of the Cathedral of Paris, it would be the same, and yet, according to Viollet-le-Duc's idea, the Cathedral of Paris — thirteenth-century work — ought to have had its façade dominated by pyramids equally of the thirteenth century. And yet it might very well have had its façade finished with towers of the fifteenth or sixteenth century, or even by campaniles with domes and colonnettes of the seventeenth or eighteenth century, and would not have been any more ugly for that. Picturesque cathedrals are not distasteful to artists.

From this point-of-view, it has been said a hundred times with perfect truth that the Cathedral of Rouen is one of the most picturesque cathedrals which one can dream of. The exterior of the choir is of the twelfth century, the nave and choir of the thirteenth, the gables of the transepts of the fourteenth; the sixteenth-century façade, set above the thirteenth-century façade, is flanked by two towers, one of the twelfth, the other of the fifteenth, and yet the cathedral is not finished. Far from it. The real Cathedral of Rouen, the one which will never be seen, ought to have seven towers. Seven towers? some will ask, that is wholly unlikely! No, we shall see shortly that Rouen should have had eight towers and Chartres nine. Nothing is easier than, not only to justify these towers, but to see how they would have looked when finished as they should have been. At the side of the façade, the tower Saint-Romain, which I have already used as an explanatory type, ought to have appeared with a campanile of the sixteenth or seventeenth century, replacing the slate-covered roof we have spoken of. As to the "Butter Tower," it lacks a stone pyramid of openwork with crockets on the arrises. The portals of the two transepts show the lower stories of four pyramids which should flank the lateral doorways. As to the central tower, the stone base of 1353, burned and repaired in 1514, was, in 1544, surmounted by a *flèche* designed by Robert Becquet, in wood covered with lead. This was burned by lightning in 1822. Later, this Renaissance *flèche* was replaced by one in cast-iron. In the drawing, I suppose that the work of Robert Becquet still appears intact, and I believe that when we think of the effect produced over the countryside by the towers of Tournai, which still exist, we can only regret the incompleteness of our cathedrals, whose picturesque silhouettes would have been so attractive and grandiose.

The Cathedral of Rheims would also have been very imposing with its eight spires, and it is quite impossible to pretend that it is much better to-day than if it had been so finished. The western towers, 80 metres in height, would have measured 120 if the spires had been built. The finish of its angle-turrets is more than suggested, only the pyramidion and the gables are wanting. The Cathedral of Rheims, seen in profile, appears still more unfinished than the Cathedral of Paris. If now we add the four transept spires, the central spire and that little *flèche* which exists above the choir, the angle-tower 18 metres in height whose base is formed by caryatides in an attitude of torture, one would be compelled to agree that, amongst the celebrated cathedrals, Rheims is one of those which would have gained most if seen completed.

Apropos, nevertheless, of restored spires or towers, and particularly of central spires, it must be said that in illustrations of this kind it is allowable to hesitate, not as to the proportions — for they are imposed by the relations of the *ensemble* — but as to the mode of construction. The original architects, lacking means, have, as is said, sometimes hesitated before the danger of too greatly overloading the isolated piers of the transepts, and they had terrible experience of this at Beauvais. Often the central spires were not built, but were replaced by a *flèche* of woodwork covered with lead, which, in spite of its really considerable weight, was far less of a load upon the lower portions of the structure than stonework would have been. But it should be added that if these same architects had had the time and the necessary resources to finish their buildings — where the original plan showed transept towers — these spire-terminated masses, buttressing the flying-butresses of isolated piers, would have rendered central stone spires far less dangerous. The Gothic building being *par excellence* a methodical construction, in perfect equilibrium, it was necessary to proceed in orderly manner and erect one after the other, according to the requirements of statics, those masses which were at once necessary and decorative.

As to the Cathedral of Chartres, which to-day we see with only two towers — and it is true that these towers are very marvels, and certainly give the countryside a superb silhouette, — what would it have been if nine towers had been built? The height of the old tower (106 metres) is exceeded by the new tower (115 metres); the four transept towers, and especially the two towers rising from the beginning of the choir, would have had less noble proportions, but the central spire would certainly have exceeded the "Münster" at Strasbourg, even if not the spires of Cologne.

But the marvel of marvels, from the picturesque point-of-view — and that is one which perhaps is least negligible — is the Cathedral of Beauvais. Not that it would ever have had against the sky a forest of spires, or towers, but because of its mere dimension, its fantastic proportions, this cathedral, if finished, would have been simply the queen of all cathedrals. Every one knows that the choir still exists, and this choir is higher than that of Cologne. This choir, of the thirteenth century, measures 68 metres in height, and the two transepts were built between 1500 and 1537.

I have placed side by side, at the same scale, the Beauvais choir and the present façade of the Cathedral of Paris. At a glance, we can perceive the difference in size. The two towers of Notre Dame de Paris could be sheltered under the roof of Beauvais, as if they were two simple soldiers sheltering under sentry-boxes. What prodigious effect would have had such a cathedral finished according to these dimensions, one hardly dares to dream! The central spire, 153 metres high, higher than the towers of Cologne, did exist — this appears hardly believable — but not for a long time, it is true. This spire, due to Jean Vast, the lantern of which was visible from the interior of the cathedral, crumbled away in 1573.

Surely the Cathedral of Beauvais would have been finished in the style of the purest Renaissance, since the transepts date from 1537; surely the western towers would have belonged to the seventeenth century, if not the eighteenth, one at the least. The Cathedral of Beauvais would have been a work of centuries; it would have been "like a mountain, in the true sense of the word, upon which each had reared according to his taste the construction which pleased him." — *Jules Adeline in Le Monde Moderne.*

BOOKS AND PAPERS

WE will begin our criticism of Mr. Gotch's book[1] with the only unfavorable observation which we shall have to make in regard to it. This is, that the appearance of the work could have been brought more into agreement with its merits by a little greater care in the management of the illustrations. From Mr. Gotch we expected, in his new book, something like his magnificent work on the Architecture of the Renaissance in England, only, of course, on a smaller scale; and, while the material is as excellent and abundant as any one could desire, it is a disappointment to see it illustrated by photographic full-page plates printed apparently at random, in all shades of color from dead black to warm sepia, mingled with half-tone cuts, scale-drawings and sketches, the last of which, in some cases, leave a great deal to be desired. It is, undoubtedly, necessary to use both drawings and photographic illustrations to explain the subject, and, in the earlier work, this was done with good judgment and excellent effect; but in the present book we find repeatedly collotype plates in brown and half-tones in black

[1] "*Early Renaissance Architectecture in England.*" A Historical and Descriptive Account of the Tudor, Elizabethan and Jacobean Periods, 1500-1625. For the Use of Students and Others. By J. Alfred Gotch, F. S. A. With 317 Illustrations. New York: Imported by Charles Scribner's Sons. Price $9.

.acing each other on opposite pages, and half-tones and pen-and-ink sketches on the same page; while, of the latter, one or two, as, for instance, that representing the staircase at Lyveden, on page 186, might almost be called discreditable. We are often told that sketching is in disrepute among English architects just now, and that we must not expect much from people who have so many other things on their hands; but there are still draughtsmen in England who can make very pretty architectural sketches, and the era of Nesfield and Norman Shaw is not so remote that one need despair of finding talent enough yet surviving to make tolerable sketches for a book which must inevitably be compared with the work of Nash and Richardson and Shaw.

Apart from this criticism we have nothing but praise for the book. Although the illustrations are necessarily small, there are a great many of them, and they show clearly the development of the Early Renaissance in England, in plan and detail; while they are accompanied with an extremely interesting and valuable text, tracing the history of the style from its timid beginnings, under Henry the Eighth, to its full assertion in the works of John Thorpe and Inigo Jones, and giving, as only an architect's writing could, exact ideas of the origin and growth of the peculiar forms of ceiling decoration, panelling, metalwork, mantels and staircases which, even more than exterior pilasters and curved gables, form the essential characteristics of the style. The lover of architectural history will read the book with very great pleasure, while the practising architect will find in it invaluable suggestions for reviving, under such modifications as the conditions of modern life may require, the spirit of a style which has always had a singular charm for the profession and the public.

It might be supposed that everything that could be said about perspective had been already said; but, to the real lover of the art of perspective drawing and sketching, there is perennial interest in learning what each new author has to bring forward on the subject; and, if Mr. Longfellow's book[1] has nothing new in the text, it would still be interesting from the skilful use made of photographs to illustrate the principles which it gives. It may be observed that the perspective of photographs is generally very false. Not only does the photographic lens give us rather the picture of a small model of the subject, seen from a distance of a few inches, than a representation of it from a point so far distant as to reduce it to the given size, but the correction for spherical aberration often magnifies the objects at the sides of the picture very materially in proportion to those at the centre, thus introducing new distortions. Mr. Longfellow, however, uses his photographs with excellent judgment, employing sometimes pictures taken with a short-focus lens, and sometimes those taken with a lens of long focus, in which the distortion is far less, to illustrate the points under discussion. With the help of these, and of a multitude of outline sketches, the beauty and cleverness of which can be fully appreciated only by the expert architectural draughtsman, he discusses in a most interesting manner, and at greater length than any other writer on the subject, so far as we know, what may be called the technique of perspective drawing: that is, the great mass of empirical rules, the result of observation, guided by good taste, with which the thoroughly accomplished draughtsman must supplement his knowledge of the mathematical science of perspective. At the very outset, for example, the learner is made to find the vanishing-point of diagonals, and is shown, by various examples the uses to which skilled draughtsmen, and, as a rule, only skilled draughtsmen, apply this invaluable key to rapid perspective drawing. Next, the student is introduced to perspective scales, so that he may, from the first, avoid the ridiculous blunders which so often disfigure the work even of people who call themselves accomplished draughtsmen.

Having explained these simple points, — which, if understood by every one who attempts perspective drawing, would do away with those pictures of the interior of churches a mile and a half long, or thereabouts; of giants stalking through streets of Lilliputian houses, and of figures poised in air above the roof of the houses that they are supposed to inhabit, which adorn the walls of nearly every exhibition-hall, — the book takes up a systematic method, which it bases on the use of the perspective plan. This, it may be observed, is a very old-fashioned method; but it is so incomparably superior to the more modern ones in the facilities which it affords for unravelling difficulties, and giving rapid approximations, as well as in its superior neatness of handling, that it has been revived of late years, and is now in general use by the best draughtsmen. Taking this as a starting-point, the book gives us some valuable observations on the choice of the conjugate vanishing-points, and the proper use of parallel perspective, with that of vanishing-points of inclined lines, adding a variety of suggestions, which the professional draughtsman will find of great value, for making inaccessible vanishing-points available; and, later, we find several chapters, as new as they are interesting, devoted to labor-saving methods of drawing circles, arches and vaults, of almost every imaginable kind, intersecting and otherwise, in correct perspective.

A draughtsman who thoroughly understands the method of the perspective plan, with its applications and consequences, hardly needs to trouble himself about other systems; and Mr. Longfellow is, to our mind, judicious in dismissing with brief notice the much-vaunted theory of curvilinear perspective. The authors of books on perspective sometimes forget that draughtsmen and artists, who have to earn a living by making correct and pleasing drawings, have no time to spend in following mathematical reasoning from doubtful postulates. They need, what very few of them possess, a thorough knowledge of one good system, which should, however, be aided by the observations which Mr. Longfellow gives in greater profusion than any other writer that we know of, and with admirable judgment, on the most advantageous choice of horizon-lines and vanishing-points; the grouping of figures; the arrangement of the composition, and many other matters which affect the success of the picture to a degree which only experienced draughtsmen can appreciate.

NOTES AND CLIPPINGS

Washington Allston. — It is remarkable that the name of the only eminent American painter who was born in South Carolina should have been omitted from the list of great American artists inscribed on the walls of the Fine-Arts building at the Charleston Exposition. The claims of Washington Allston to a place in the list are thus set forth in a letter written by Edward Octavius Flagg to the *Mail and Express* of New York. "If he were not mentioned as handling the brush equal to these, his compeers, there are other reasons why he should be enrolled on the immortal list. As a painter alone, while in Florence, he was styled the Titian of America. He was in this regard most highly appreciated in Europe, where his best pictures are to be found. He produced a portrait of Coleridge which his friend Wordsworth, echoing a common sentiment, pronounced a masterpiece. All of his choicer productions have long been deemed full of suggestiveness, classical merit and idealism which belong to a pure and exalted imagination. Aside from the painter, other considerations would seem to have weight in determining an honorable award on the part of his judges and room where it is denied. His humanity was displayed when, at a great sacrifice, he freed his slaves. His society was widely sought by those who would enjoy an entertaining and improving converse. He stood among the first as a scholar, poet and prose writer. Mrs. Jamison said that he was one of the three great men of America in her day. He was born in South Carolina, and had not ceased to shed lustre upon his native State from the time when he delivered the poem at his graduation from Harvard until the day of his death. Boston has honored him by placing at the entrance of her Art Museum his splendid conception of "Belshazzar's Feast," also by calling after him a gallery in the same, likewise a street and an adjacent town. [Not a town, but a railway-station neighborhood in the city. — Ed.] In the new art-gallery at Washington his name is inscribed in mosaic. The following is the list of painters referred to: Benjamin West, Gilbert Stuart, John S. Copley, Thomas Sully, George Inness, A. H. Wyant, Homer Martin, George

Fuller. Allston was certainly superior in rank to some of these. Another name that should have appeared is that of Frederic E. Church, who was altogether the greatest man in landscape whom America has yet produced.

THE VILLA BORGHESE. — The Villa Borghese and its famous gardens at Rome have been purchased by the Italian Government. The gardens will be united with the Pincio, and the Borghese villa will become another public museum. Payment will be distributed over ten years. In all probability the Government will sell the gardens to the municipality of Rome, but if this be impossible the land can be sold to private parties. The King is to erect a monument to his father, Humbert, in the Borghese Gardens, and the Government will establish on a portion of the land an agricultural college. The collection in the villa includes the Titian which a modern expert has identified as a scene between Aphrodite and Medea, the enchantress, famous under the title of "Sacred and Profane Love." There are also the "St. John the Baptist in the Desert," by Paolo Veronese, the famous "Danaë and the Rain of Gold," by Correggio, and the Raphael, painted in 1507 at Perugia, the celebrated "Deposition from the Cross." — *Boston Herald.*

LONDON'S DEADLY WATER-SUPPLY. — The life of a Londoner is worth ten to fifteen years' less purchase than that of the average provincial. This fact is due to many causes, but the chief among them is the quality of the water. London water is "hard." That is to say, it contains a large quantity of the carbonate and the phosphate of calcium. The tea-kettle proves this. When a Londoner examines his tea-kettle he must be horrified to think what the condition of his stomach must be. But the tea-kettle reveals only a fraction of the state of affairs. When water is boiled the carbonic acid which held part of the calcium in a state of solution (and therefore invisible) is driven off and the solid calcium falls to the bottom. But boiling has no effect on the phosphates. They still remain in solution, and are swallowed in our tea and coffee. Now, barring fatal disease, the chief cause of decay and death is calcification of the blood vessels. This prevents proper circulation of the blood and produces apoplexy. In London water we swallow enough stony matter to shorten our lives ten or a dozen years. Drinkers of soft water escape this life-destroyer, and hence most provincial people live longer than Londoners. The moral is that every Londoner ought to welcome the day when fresh sources of supply will be available. The Welsh water, which the London County Council hope some day to obtain, has very little calcium salts, and it should prolong the life of its consumers by many years. — *London Mail.*

TRANSMURAL VENTILATION. — In the year 1878 Dr. Flugge proved that air will go through the walls of a closed room, at a rate depending mainly on difference of temperature between the inside and the outside — the latter being the lower. With walls of ordinary thickness he found that about one-fourteenth of the air in the room would be changed per degree Centigrade per hour. In other words, if the outer were 14 degrees Centigrade colder than the inner, the air of the room would be completely changed in an hour by transpiration through the walls. M. H. Wolpert has re-examined this subject, and he finds that in a chamber of 60 cubic yards capacity, having walls of masonry covered with paper, the air will be changed at the rate of one-fortieth of its volume per degree Centigrade per hour. When the paper on the walls contained oil-varnish decidedly less air permeated, while without paper at all much more went through. It is desirable, therefore, that the exterior of houses should be clean, and a heavy rain is a blessing in this respect. Also it follows that the greater the difference between inside and outside warmth the more copious this spontaneous ventilation. Pettenkofer found that when materials like slag and glass were used, through which air could not pass, the cements employed were, as a rule, highly permeable. — *London Telegraph.*

BOGUS ANTIQUE TAPESTRIES. — The two curiosity dealers who were arrested for doctoring new tapestry and selling it for old, have just been condemned to six months' imprisonment and 1,000 francs fine each. The principal culprit was, it appears, Charlanes, who had failed as an upholsterer, and who, being hard up, had the brilliant idea of buying new Aubusson tapestry, doctoring it, and selling it as old. He had two accomplices, Deschamps, who has made himself scarce, and Sauvageot, who shared his condemnation, and the trio used to sew on to the modern tapestries antique linings, stain parts of them with walnut-juice, rub them with wet earth, powdered pumice-stone, soft-soap, and other products, scent them with camphor or "naphthaline," and all this with "intent to deceive." Charlanes took the treasures, once doctored, into the provinces and sold them to unsuspecting persons as the possessions of aristocratic families who had been obliged to dispose of them. One unfortunate lady who had bought a set of panels for 13,000 francs showed them afterwards to an expert, and then the murder was out. To people interested in tapestry and having a knowledge of it the whole affair is surprising, for hand-made and machine-made tapestry are so utterly different. — *London Globe.*

BOLOGNA'S LEANING-TOWER IN DANGER. — Bologna has been having a sensation in the rumor that its great leaning-tower, the pride of the city, is weakening, and may fall. This has caused so large an influx of visitors that it is said the hotel-keepers may not be wholly guiltless in regard to the rumor. The city has two of these square towers, the Asinelli, which is 315 feet high, and was erected in 1109, and its rival, the Garisenda, which was built one year later, and was originally much higher, and is rendered peculiar by its decided inclination to one side. It is now only 153 feet high, the width of one side is 23 feet, the walls at the base are 6 feet 6 inches thick, while higher up they are 4 feet 9 inches. Its origin is somewhat obscure, but it was certainly intended to outdo the Asinelli, and both were for retreat in troublous times. Some say the original intention was to make it lean, but others contend that either the ground has settled or there was a defect in the engineering. This unique relic was so little thought of by one of its later possessors that it was sold in 1266 for 220 lire, something less than $44. — *N. Y. Tribune.*

NEW YORK'S FIVE TUNNELS IN POSSE. — These are some of the more important features in the Pennsylvania Long Island railroad plan for running direct to New York City by tunnels: There are to be five tubes, three under the East River and two under the North River, all joining at a central station in a space at Seventh and Tenth Avenues, Thirty-first and Thirty-third Streets. The station is to be one of the largest ever constructed, measuring 1,500 feet in length by 520 feet in width. Leading to it will be 15 miles of tunnels. The tunnels will have an inside diameter of 18 feet 6 inches. There will be a single track in each. There will be a total of 25 tracks in use at the central station, which is to be three-decked. Electric-motors will be employed in hauling trains through the tunnels. It will put Long Island relatively as close to the centre of New York City as the Bronx is now. By means of a second tunnel under the Hudson River, distinct from the gigantic plan of the Pennsylvania railroad, this city is to be connected with Philadelphia by trolley. E. F. C. Young, President of the North Jersey Street Railway Company, has purchased the old Hudson River tunnel for this. — *Boston Herald.*

THE ALBERT MEMORIAL, LONDON. — It seems incredible that so important a public memorial as that erected in honor of the late Prince Consort in Hyde Park should be neglected. The London atmosphere is no respecter of persons or works of art, and the Albert Memorial appears to be destined to the common deterioration. Only thirty years have elapsed since it was completed, and yet Mr. R. M. Beachcroft has reported that during a visit on Sunday last a shower of mosaic from one of the gables fell at his feet. He was also informed that such a fall is of frequent occurrence. Some of the statuettes have been already disfigured owing to the softness of the marble, and the railing and gates are in a neglected condition. So elaborate a structure was unfitted to be placed in the open air of London. The delicate detail and the variety of materials employed appear to offer facilities for the inevitable process of disintegration, and only good work could have stood so long. On the other hand, it should be remembered that restoration is particularly difficult. Scaffolding would be regarded as an eyesore, and it would not be easy to employ a movable platform, from which reparation would be practicable as soon as needed, and which could be taken away when the work was executed. The Memorial, however, deserves careful attention. When decay once begins, it is apt to advance with unsatisfactory speed, and, in order to preserve a work in which so many artists coöperated, it may be necessary to enclose the Memorial in a shrine of glass, which would not be inappropriate in Hyde Park. — *The Architect.*

GALVANIC COLORING OF METAL. — In an abstract by *Lightning* of an article in *L'Electrochemie* on the coloration and protection of metals, a large number of receipts are given. Gilding on steel is imitated by galvanically coating with copper from a cyanide bath, then with a thin film of zinc. After drying and polishing, the article is heated in linseed-oil to 160 degrees Centigrade, when it is stated that the surface becomes of a red-brass color, as if there had been a real alloying of the copper and the zinc. Iron can be protected from rust by a layer of molybdenum, deposited from a bath containing one gramme of ammonium molybdate and fifteen to twenty grammes of ammonium nitrate per litre, with a current of two to five ampères per square decimetre. All varieties of iron can be covered with an adherent and unalterable deposit of peroxide of manganese by making them anodes in a bath containing about .05 per cent of manganous chloride or sulphate, with 5 to 25 per cent of ammonium nitrate, the bath being cold, the cathodes of carbon, using a weak current of one to two ampères. Selenite of copper is recommended for coloring iron and steel brilliant black or blue-black, according to the strength; the layer, after firing, is very permanent. The bath is made with selenious acid six to ten, copper sulphate ten, nitric acid four to six, to the litre of water. It can be also used for copper and brass with feeble currents. Mathey colors watch-hands and other small metal articles with gold or platinum, but not with silver, by placing them on an anode plate under about three cm. of solution, and dipping the cathode into the liquid over them until the required tint is produced. — *N. Y. Evening Post.*

INSURANCE GRAVEYARD. — Franklin Webster, editor of the *Insurance Press*, has made a very interesting compilation of underwriting corporations that have retired from business in the United States during the last two or three decades. The summary is rather appalling, and shows how narrow is the margin of profit obtainable from the business to-day, Mr. Webster speaks thus of the exhibit: "The *Insurance Press* knows no better way to emphasize the magnitude of the problems confronting fire-underwriters, to demonstrate the unwisdom of legislative attacks on the insurance business, and to explode the fallacies concerning insurance "profits," than to ask the American people to gaze upon the list of joint-stock fire-insurance corporations that have given up the struggle, and to reflect upon the causes of the failures The object-lesson is impressive. The *Insurance Press* has invited and received the coöperation of insurance-departments in making up the record that follows, and has made use of other data, especially reports by the National Board of Fire-underwriters. During the past twenty-five years the fire-loss in the United States has exceeded $2,800,000,000. This year the value of the property destroyed by fire will exceed $170,000,000. Nearly 1,200 fire-insurance companies with paid-in cash capitals, mutual companies not included, have gone to the wall in the United States. Nearly all of these companies have been either burned to death or crushed out of existence by oppressive laws.

NOTES AND CLIPPINGS. 16

TOO late in the season to allow us to perfect our plans and make announcement earlier, we determined to make a change in the manner and method of publishing our International edition, and we now give notice that the change impends and will have effect in the second quarter of the year. The change consists simply in gathering the extra illustrations which constitute the International edition into four quarterly issues in place of their being, as now, scattered through thirteen weekly issues. The result will be that the subscriber to the International edition will receive each week a copy of the Regular edition and with each quarter a quarterly volume in which will be collected the gelatine and other International plates. That is, a subscriber will receive exactly what he now receives, but it will reach him in what, we believe, will be a more acceptable and agreeable form. Amongst other advantages incident to this condensation of matter is the fact that it will enable us to publish in the same issue all the plates in illustration of a given building, instead of being forced to let them dribble out, a few at a time, in four or five different weekly issues, as in the past. — *From our issue for Jan.* 4.

THE building statistics of New York show a remarkable decline in the building of single houses within the last decade. In the year 1890 plans were filed for eight hundred and thirty-five single dwellings. Since then, the number has diminished annually, and, for 1901, the total is only a little more than one hundred. Evidently, the change is due to the increasing disposition of the inhabitants of the city to live in tenements or flats, but the fact that they like to live in tenements is itself of importance. It is not very many years since the only tenement-houses known in New York were those for the very poor, and it was with a certain disapprobation that the New Yorkers observed the experiments made in Boston in the way of providing "apartment-houses" for well-to-do people. A little later, some large apartment-houses on the Boston plan were built in the most fashionable quarters, so as to attract tenants who wished to count as dwellers on Fifth Avenue or Fifty-ninth Street without having to pay the enormous rents demanded for single houses on those thoroughfares. These houses proved very successful, and the fashion spread rapidly, until even the modest dwellings on the side streets are now, to a great extent, replaced by four-family flats, new single houses being built, at present, almost entirely for the very wealthy.

WHETHER the change is altogether advantageous is, perhaps, uncertain. There is a great deal to be said in favor of the one-family house, with its privacy and ample space, and its provision of parlors for entertaining friends; but entertainments in private houses are rather out of fashion in New York, even among the very rich, who find it easier to give balls at Sherry's or Delmonico's than at home, and the great majority of the inhabitants of the city can ill afford such expenses. In Paris, where dwellings have been for centuries divided, as they will soon be in New York, into "hôtels" for the very rich, and tenements for every one else, the people who live in apartments find no difficulty in holding their weekly receptions, and giving dinner-parties; and it is not certain that the afternoon teas in their modest parlors are not, after all, as pleasant to the participants as the crush of miscellaneous people at a general reception in this country.

AS for the privacy of the single house, as compared with the apartment-house, it should be remembered that the latter may, by proper planning and management, afford nearly or quite as much privacy as the individual dwelling. The earlier apartment-houses in New York were modelled after the pattern of hotels or club-houses, on the supposition that they would be occupied by congenial people, who would like to meet in the common reception-room or restaurant. Time has, however, shown that the tenants of such houses change so frequently that it is impossible, and often undesirable, to cultivate intimacy among them, and the tendency is now toward the Paris system, in which no common rooms are provided, outside of the *concierge's* lodge, in which a stranger may occasionally be accommodated, but in which, also, by putting the whole building under the guard of the *concierge*, a certain privacy is secured for all the apartments, which is very pleasant.

THE "Columbus Circle," in New York, where Broadway, Eighth Avenue and Fifty-ninth Street intersect, has long been an object of anxious study on the part of people interested in municipal improvements, partly on account of its artistic possibilities, as the centre from which seven crowded thoroughfares radiate, and partly on account of the increasing necessity for making some provision for the safety of the people who have to cross it, or be transferred from one to another of the three lines of surface-cars which meet there. The Rapid Transit Subway is now built beneath the Circle, and will have a station there, so that the importance of securing the safety of the public will soon be greater than ever. Under these circumstances, the Municipal Art Society has been thoughtful enough to have a plan prepared by Mr. C. R. Lamb, whose interest in such matters is well known in the profession, for modifying the present arrangement of surface tracks, and, incidentally, the general disposition of the Circle and its principal ornament, the Columbus Monument, which stands in its centre.

MR. LAMB'S idea for the treatment of the latter, as shown in the New York newspapers, consists in raising it on top of a circular colonnade, two stories high, which is roofed over, and is intended to serve as a shelter for people waiting for transfer between the surface-lines. It cannot be said that the newspaper presentation of this part of the scheme is extremely successful, as a matter of design; but architects will agree that the idea has great possibilities, and it is not likely that Mr. Lamb really designed the circular portico, with columns about their own length apart, which the newspaper artists produce as his work. In regard to the plan of the remodelled Circle we imagine that the profession will have nothing but praises. The tracks which now intersect nearly in the middle of it are, by Mr. Lamb's scheme, turned out of their direct lines, so as to form arcs of two concentric circles, with the Monument in the middle. The two circles provide a double track for all the lines, and they are so far separated as to admit platforms between them, which serve not only as "islands" of refuge for pedestrians crossing the Circle, but as safe standing-places for passengers waiting for their cars. The Subway Station is outside of the surface-tracks, and is entered from the sidewalk, after the fashion of the new Metropolitan stations in Paris, the sidewalks around the Circle being made of ample width for such purposes.

MUNICIPAL AFFAIRS, one of the most interesting of the quarterly magazines, appears with a collection of valuable illustrated papers on the "Decoration of Cities," published with the coöperation of the Municipal Art Society. The proof-reading of these papers leaves something to be desired, and it is difficult for a person, sensitive on the point of spelling, to read of the "Piazza di S. Pedro," in Rome; the monuments of "Victorio Emanuelo," and "Christopho Colombo," in Genoa; the "Arch de Triomphe," in Paris, and the "Shöne Brunnen," in Nuremberg, without a small shudder; but the matter is otherwise good, and the illustrations are very pretty. Mr. Lopez, who writes on "Municipal Sculpture," well says that New York, with its beautiful approach from the sea, and its magnificent views over the Hudson and the Sound, is unrivalled among great cities for natural advantages; and he appeals for a greater public interest in adorning it with works of art worthy of its situation and its wealth. He observes, with justice, that even the sculpture now existing in public places in New York is, as a rule, "deplorably placed," so that while good statues lose the effect that they might have produced, even the poor ones, if judiciously arranged, would be quite tolerable.

IN regard to mural painting, Mr. Charles M. Shean, a very competent authority, calls attention to the lack of interest of Americans in the decoration which, in Europe, is regarded as essential to the completeness of a public building. There is no question that, as he says, American artists are quite competent to do such decorative work, but nobody seems to think of employing them. Now and then, it is true, the architect of some very costly public building succeeds, by herculean efforts, in persuading his building-committee to employ a good artist in painting a few panels, or, possibly, a ceiling; but the example is not followed; and where, in Belgium, or in some parts of Germany, even a village church would be decorated, often gratuitously, by accomplished artists or students of art, we find, in this country, such buildings, as a rule, ornamented either with stencilled diaper-work, of the oil-cloth order, or with mosaic, so enormously expensive that it is usually confined to a glaring little patch in the most conspicuous position near the front door. It is possible that something might be done, that has not yet been done, to disabuse the minds of the public in regard to the cost of painted decoration. Reading, as most people do, in the newspapers that a certain artist has contracted to paint a ceiling in a new court-house for forty thousand dollars, they conclude that mural painters are incapable of distinguishing with the naked eye any sum less than ten thousand dollars; and, not wishing to run the risk of a humiliating rejection of any suggestion of a smaller amount, as compensation for what they would like to have done in their houses, they content themselves with a less aspiring form of art. Now, the fact is that nine artists out of ten who could decorate a room with beautiful works, which would be a perennial delight to their owner and his friends, have never seen ten thousand dollars together in their whole lives; that, instead of being lordly persons, who, at home, roll in heaps of gold, they are quiet, modest people, who love to paint above everything else, and, if they can be sure of a very unambitious recompense, will gladly place out their best talent at the service of a considerate and sympathizing patron. Travelling people who have seen, for instance, the beautiful series of frescos in the cloister of the Insel Hotel, at Constance, explain their existence by saying that "artists in Germany work so cheaply"; but artists in America work just as cheaply as they do in Germany, and what the proprietors of the comparatively small Insel Hotel could afford to do, the owners of hundreds of American establishments of various kinds could do much more easily. In fact, hotel proprietors in this country are already known as patrons of the arts, presumably for the sake of profit. The Hoffman House "Bouguereau," in New York, has probably brought in to its owners many times its cost, which was certainly not trifling; and most architects can recall lesser attractions which serve a similar purpose in other hotels. We should be far from saying that all art should have a commercial purpose, or that hotels were the best place for the display of the fine arts; but a picture painted to please hotel guests is better than no picture at all; and the people who see good painting in a hotel may be thus reminded of the possibility of having something of the kind in their dwellings.

A VERY peculiar step in industrial matters, and one very honorable to all parties concerned, has been taken in a shoe-manufactory in New York. Some years ago, there was a dispute over wages in the factory, and, after it was settled, both employers and employed came to the conclusion that, for the future, it would be for their interest to settle their differences by arbitration. An agreement was therefore made, by which both sides agreed, in case of need, to refer such controversies to a committee of five persons, two to be chosen by the firm, two by the employés, and the fifth by the other four. It was agreed that the award of this committee should be final; and, as bodies of workingmen are not remarkable for their fidelity to their engagements, it was provided that each party should set aside a guaranty fund, to be forfeited in case it failed to abide by the award. The firm deposited at once the sum of ten thousand dollars for this purpose, and the employés paid out of their earnings a small sum each week, until each man had twenty-five dollars, and each woman fifteen dollars, invested in the fund, which was, with a confidence which is pleasant to note, held in trust by the firm, drawing interest at six per cent. Recently, the firm adopted a newly patented method of making lasts, which, in the judgment of the workpeople, increased the labor in some respects, and, in one department, they asked for an increase of one cent per pair in wages. The firm refused, thinking that the labor was not really any greater with the new process, and the question has now been referred to the arbitration committee, with the certainty that its award will be accepted by both sides, without interrupting the work, damaging the business of the firm by failure to meet contracts, or throwing poor people out of employment in the middle of winter.

A BILL is before Congress, supported both by the McKinley Memorial Association and the McKinley Memorial Arch Association, providing for a Commission to secure a site, and obtain plans and models, for a memorial arch, to be erected in the District of Columbia in honor of the late President. The bill provides that the Commission may pay to competing artists a sum not exceeding twenty-five thousand dollars "for plans, specifications and models." What this means is not very clear, and we cannot but regret the delay in the constitution of the long-desired National Art-Commission which would be enabled to have such projects laid before Congress in proper shape. If the bill proposes to set apart only twenty-five thousand dollars for all the artistic work in connection with the intended arch, the scheme might as well be abandoned at once; but if only preliminary designs are to be received in competition, the fact ought to be made plain. Whether a triumphal arch calls up most effectively the considerate kindness characteristic of our lamented President is a question which admits of discussion; but the artists do not have to decide it, and, under proper management, any form of memorial that may be preferred can be made creditable to American art.

CONTRACTORS and dealers in building materials should take note of a recent decision by the highest court in England. A certain corporation known as Steward and Company, which owns the Portland stone-quarries, was invited by the British Admiralty to submit a tender for stone, in such quantities, and at such times, as the Admiralty might require. Steward and Company replied, offering to furnish stone, to an approximate amount of two million tons, at a certain price. The Admiralty accepted the proposal for a supply of "about two million tons or such quantity as may be required." Later, the Admiralty gave notice that it had made a contract for its building work, and would not need any more stone. Steward and Company sued for the completion of the contract which, as was claimed, the Admiralty had made to take "about two million tons" of stone, and obtained a favorable decision, but the House of Lords reversed the decision, on the ground that the expression "about two million tons" was too indefinite to make the contract one for a specific quantity.

MR. HENRY RUTGERS MARSHALL, President of the New York Chapter of the American Institute of Architects, and Mr. John De Witt Warner, President of the Municipal Art Society, have been appointed members of the New York Municipal Art-Commission, to succeed Mr. C. F. McKim and Mr. Charles T. Barney, whose terms have expired. We need hardly say that, while the friends of public art will regret the retirement of Messrs. Barney and McKim, who have done much, not only to improve the city, but to educate public sentiment, their successors will have the entire confidence of the profession, and of artists everywhere.

THE AMERICAN VIGNOLA.[1]—VI.

PART I.—THE FIVE ORDERS.

GEOMETRICAL RELATIONS.

THE dimensions and proportions set forth in the previous paragraphs, and recapitulated in the Tables, enable one to draw the Five Orders, according to Vignola, with great accuracy and sufficiently in detail for all the ordinary purposes of the draughtsman and designer. The figures for the larger features are easily remembered, and the smaller divisions and subdivisions can for the most part be obtained by dividing the larger into two, three, four, or five equal parts.

But besides these arithmetical proportions some geometrical relations may be pointed out which are calculated greatly to facilitate the work of draughtsmanship, drawing being naturally more closely related to Geometry than to Arithmetic.

LINES AT 45 DEGREES.

The proportions of any figure that is as wide as it is high, and which can accordingly be included within a square, are most easily determined by drawing the diagonal of the square, that is to say, by drawing a line with a 45-degree triangle. Such figures are, as is shown in the Illustrations, the projections of: —

1. The Echinus, in the Tuscan, Doric and Ionic Capitals (83, 84).

2. The Abacus, in the Tuscan and Doric Capitals (83, 84).

3. The Astragal, in all the Orders.

4. The Architrave, including the Tænia, in the Tuscan and Doric Orders, counting from the axis of the Column (83, 84).

5. The Tænia itself, and the Cymatium which takes its place (83, 84).

6. All the Cornices, except the Doric (83).

A line drawn at 45 degrees through the Doric Cornice gives, where it cuts the upper line of the Cornice: —

7. The face of the Corona, in the Denticulated Doric (84).

8. The face of the Mutule in the Mutulary Doric (84).

A line drawn at 45 degrees through the Doric Architrave and Frieze, from a point on the axis of the Column and of the Triglyph, taken either at the bottom of the Architrave or at the top of the Frieze, gives: —

[1] Continued from No. 1352, page 61.

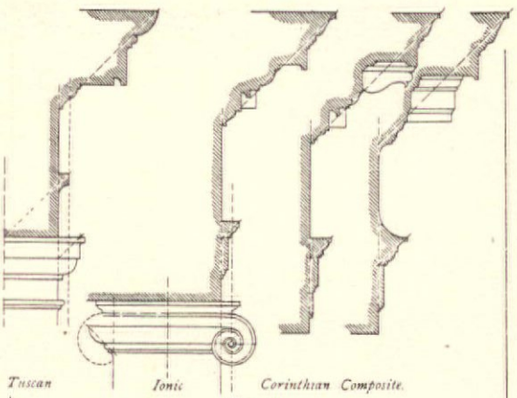

Fig. 83.

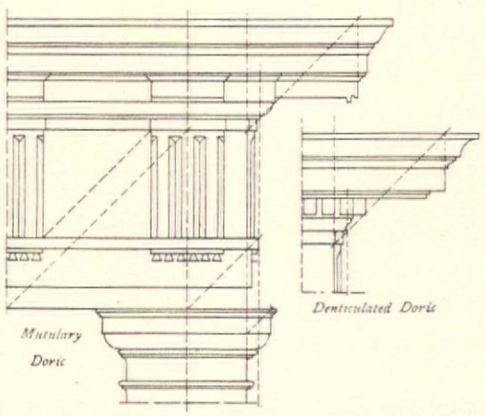

Fig. 84.

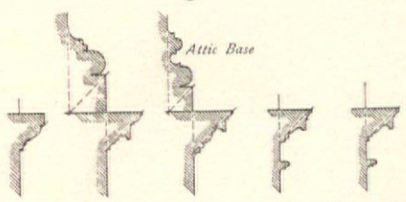
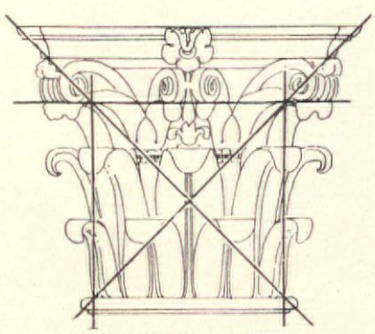


Caps of Pedestals.
Fig. 85.



THE CORINTHIAN CAPITAL.
Fig. 86.

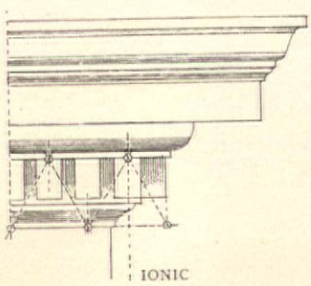


Fig. 87.

9. The Axis of the next Triglyph, and so on (84).

A 45-degree line also gives: —

10. The Caps of the Pedestals, except the Tuscan (85).

11. The Plinths of the Doric and Attic Bases (85).

Lines drawn at an angle of 45 degrees across the Corinthian Capital from the extremities of its lower diameter give (86): —

12. The width of the Abacus.

Where they cut the line of the upper diameter of the shaft, extended, they give: —

13. The Depth of the Scroll.

LINES AT 60 DEGREES.

In like manner, lines drawn at an angle of 60 degrees through the Bed-mould of the Ionic Cornice from a point on the axis of the Column, taken either on the upper line of the Frieze or on the upper edge of the Dentil Band, give, where they touch the upper line of the Frieze and the upper line of the Dentil Band: —

14. The Axes of the Dentils, and the outer face of the Double Dentil (87).

Similar lines drawn at 60 degrees in the Corinthian Cornice, taken from a point where the axis of the Column cuts the lower edge of the Corona, give,

(*a*) Where they cut the lower edge of the Corona, the upper line of the Frieze, and the lower line of the Ovolo: —

15. The Axes of the Modillions and of the Dentils, and the outer face of the Double Dentil, very nearly (88).

(*b*) Where they cut the lower line of the Modillion Band: —

16. The width of the Modillion, and the outer face of the Modillion Band (88).

(The distance from the edge of the Corona down to the lower edge of the Modillion Band is one-third the distance down to the top of the Frieze, and the distance down to the lower edge of the Ovolo, one-half.)

THE IONIC CAPITAL.

A line *cb* drawn through the Eye of the Ionic Scroll parallel to the line *CB* shown in the figure, gives,

At its intersection with the lines that define the top and bottom of the Scroll: —

17. The limits of a Fret within which the Scroll can be constructed (89).

VERTICAL LINES.

The outer line of the upper Diameter of the Shaft gives, in all the Orders (83, 84): —

18. The face of the lower band of the Architrave, and

19. The face of the Frieze.

In the Denticulated Doric, it gives (84): —

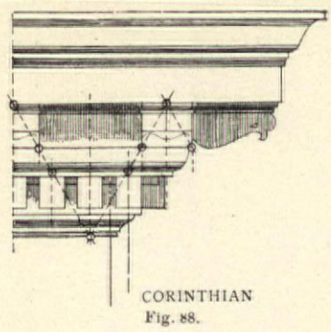
20. The outer face of the first Dentil, next the Double Dentil.

In the Ionic and Corinthian Orders, it gives (83, 84): —

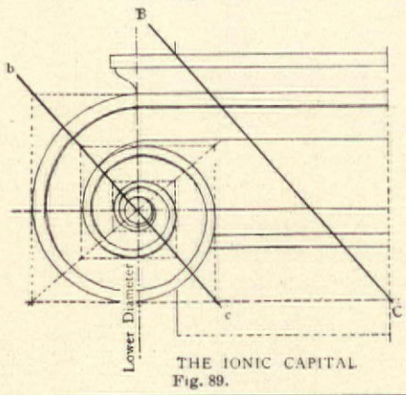
21. The axis of the first Interdentil.

The outer line of the lower Diameter of the Shaft, produced upwards, gives (83, 84): —

22. The projection of the Astragal,



CORINTHIAN
Fig. 88.



THE IONIC CAPITAL
Fig. 89.

in all the Orders, except the Tuscan and Doric.

23. The projection of the Tænia, in the Tuscan and Doric.

24. The projection of the Fillet, in the Bed-mould of the Mutulary Doric.

25. Twice the projection of the Triglyph, which is seen in profile.

26. Half the projection of the Tuscan Bed-mould, of the Tuscan and Doric Abacus, and of the Doric Mutule Band.

It also gives: —

27. The Axis of the Extreme Dentil, or first half of the Double-dentil, in the Denticulated Doric, Ionic, Corinthian and Composite Orders.

28. The position of the Eye of the Ionic Scroll, which is on a level with the bottom of the Echinus.

W. R. WARE.

[To be continued.]

ABINGDON, BERKSHIRE, ENGLAND.

ABINGDON is a very ancient town, the seat of royalty in Saxon times, and of a great abbey founded in 686 by King Cædwalla, for twelve monks of the Benedictine Order with rich endowments. The Danes demolished it in Alfred's reign; and by reason of the monks' indifference to the King's work in defeating their enemies or their inability to give him substantial help, the King took away from the Abbey its ownership of the town. Alfred's grandson Edred restored the possessions of the convent, and laid the first stone of the monastery, which, from being one of the largest in England, is now laid lower than the ruins of many of its contemporaries. It became a mitred abbey with huge possessions, far and near. Even in the Norman survey it had more than thirty manors, and at the dissolution it was valued at £1,876 10*s.* 9*d.* Hence, probably, the envy and hatred of the townsfolk, for in 1326 they wickedly and sacrilegiously plundered it.

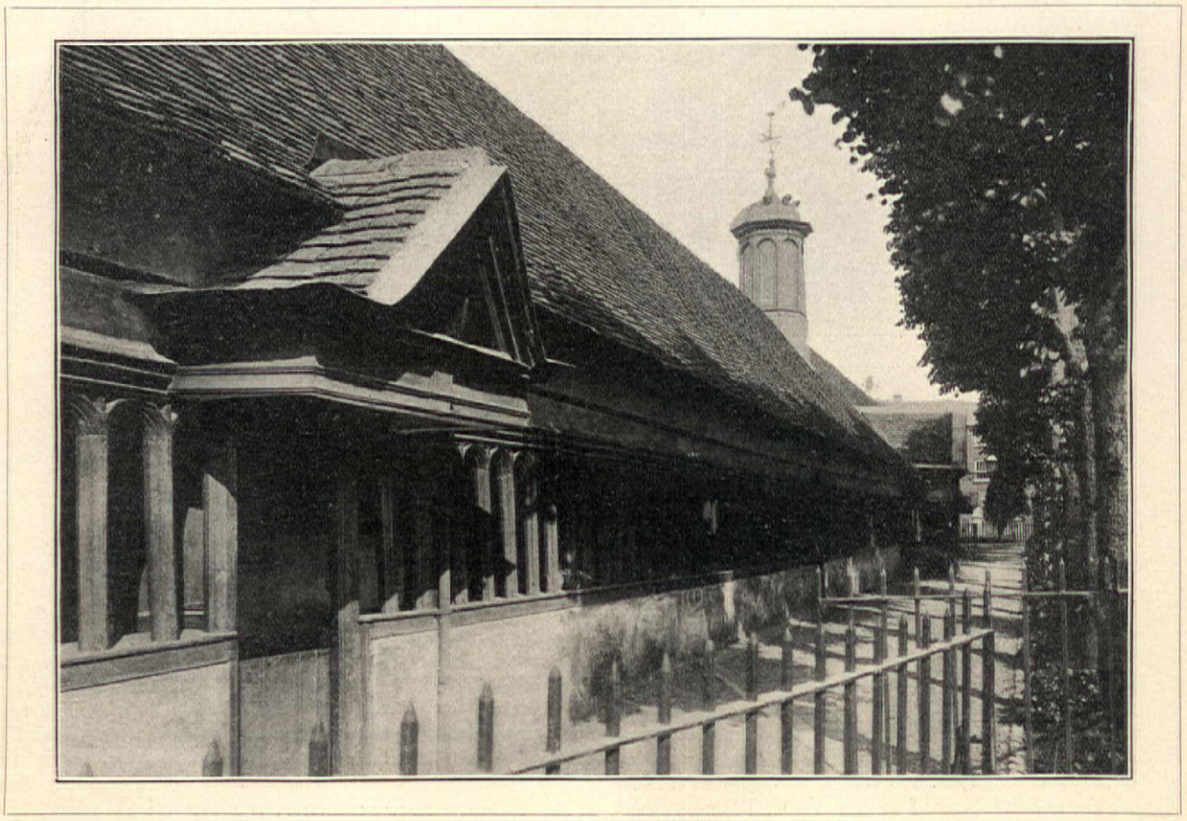
Church of St. Nicholas, Abingdon.

Leland speaks of it as a magnificent pile of buildings in his time, ranging in architectural styles from Early Norman to late Perpendicular. It is now only a gateway, probably preserved through having been used as a jail, and some walls and fragments of windows in a building, the property of, I think, a brewer. The last abbot surrendered to the King, and thereby earned a pension of £200 a year, with permission to keep his country-house of Cumnor (of Amy Robsart fame).

Church of St. Nicholas and Christ Church Almshouses, Abingdon.

Cilla, sister of King Cædwalla, founded about 690 a nunnery near the Abbey, in honor of St. Helen, but it was removed later on to Witham, and St. Elen's became a manor in secular hands. In 1427 it belonged to the fraternity of the Holy Cross, and descended to the trustees of Christ's Hospital (in Abingdon), to whom it was given by Edward VI.

The Church of St. Nicholas was built about 1300, it is said, though the west door is certainly of older date. The tower is supported by a west wall with a small arched aperture at the end of the nave.



Christ Church Almshouses, Abingdon.

St. Helen's is a five-aisled church of late fifteenth century. It was built for a guild in 1539, by one R. A. who was buried in the altar-tomb in the north wall. One of the fraternity of the Holy Cross, Nicholas Gould, "ceiled" Our Lady's aisle in in the reign of Henry VI.

"In the worship of Our Lady
Pray for Nicholas and Amy,"

said the inscription.

England was always noted for large families, as we may see by a tablet which records that Mr. William Lee, who died aged ninety-two, had seventeen children (two wives), seventy-eight grandchildren, and one hundred and two great grandchildren — "that he had in his life-time issue from his loynes two hundred, lacking but three" (*Ashmole's Collections*).

A curious entry in the parish register shows that the spring assizes were held at Abingdon. "1569 — buried the 3 day of Marche, Margery Towseye, widdow, who was, at the assize then holden, quite of wichecrafte layde to her charge, and dyed this day in the streete, sodenlie, as she was going on her business."

The brotherhood of the Holy Cross was instrumental in building the bridges at Burford and Culhamford. The fraternity was incorporated by royal charter in 1442, and possessed land at £40 per annum for the purpose of keeping the road between Abingdon and Dorchester in order, and for the maintenance of thirteen poor men and women. The great cross erected by the brethren, "a goodly piece for beauty and antiquity," was "sawn down," by Waller's army, during the Civil Wars. In 1457 the brotherhood was well-to-do, and upon the day of the Invention of the Holy Cross (3d May) they made "a bountiful feast, unto which came many of the brethren and sisters of the society." They spent, usually, "6 calves, costing 2*s.* 2*d.* each; 16 lambs, 12*d.* each; 80 capons, 3*d.* each"; above "80 geese, 2½*d.* each; 800 eggs, at 5*d.* a hundred, many marrowbones, much fruit and spice, great quantities of milk, cream and flour." (Wheat was sold at 12*d.* a quarter in the thirty-third year of Henry VI.) They also had much sent them by their tenants. But, besides themselves, they had "twelve priests to sing a dirge," to whom they gave "4*d.* for their pains." They also had twelve minstrels, "to make them merry" (after the dirge?), to whom 2*s.* 3*d.* apiece was given, "besides their diet and horsemeat." They also had processions and plays, and games to "captivate the senses of the zealous and to allure the people into greater liberality." Those who sat at dinner paid one rate — those who stood, another.

At the first endowment of Christ's Hospital out of the funds of the brotherhood of the Holy Cross, the thirteen poor men and women received each about £6 a year and their "liveries."

A new building was erected in 1718, and eighteen "poor persons received 6*s.* 1*d.* a week each, and clothes every two years. The original building has been much repaired, but its character, and its material, timber and plaster, have been preserved. It has a corridor the whole length of the building from which the doors of the houses are entered." It is "draughty," the old folks say; but a covered way in the air must be a boon when fetching water, and a refreshment as a summer sitting-place. On the gabled front is an allegorical painting representing the duty of almsgiving, with portraits of Edward VI and Sir John Mason. Inside is a fine timbered hall with old furniture and portraits — not of value from the art point-of-view. At the back of the house is a fine old-fashioned garden. At the end of the building by the river is a "Crucifixion" under glass.

The Abbey Gateway, Abingdon.

Elfrida, who induced King Eadgar to kill her husband Æthelwold, and caused the death of Edward the Martyr (buried in the Abbey), held lands at Abingdon, but after the family troubles she retired to the Abbey of Amesbury. The Perpendicular gateway of the Abbey and the walls and windows near by are all interesting fragments of the great foundation which rivalled Glastonbury, Shaftesbury and St. Albans. The refectory has an open-timber roof, Decorated window and Henry III fireplace. The Norman church is described by Leland as being 560 feet long, with twenty-four columns on each side.

Henry III kept court at Abingdon in 1276. The town is well worth visiting from Oxford, and, with Cumnor and other places, is, historically, most interesting. S. Beale.

TECHNICAL SCHOOLS OF GERMANY.

No country does so much for the education of its people as Germany. The common schools are not only in reach of the poorest, but the tuition is free and attendance is compulsory in childhood. Hence, ignorance is a crime, and illiterates are no more numerous than criminals. Having passed through the common schools,

the young men and women of the country have an opportunity to qualify themselves by special training for any one of the ninety and nine occupations. In the university every branch of science is taught, and every path of learning may be followed as far as the ambition of the student prompts him to go. For those who prefer, or whose circumstances require them, to engage in commercial, mechanical or agricultural pursuits there are schools for training the hands as well as the minds for any department of human activity. There are schools for farmers, gardeners, florists, fruit-growers, foresters, blacksmiths, carpenters, machinists, cabinetmakers, bookkeepers, tailors, shoemakers and druggists; there are cooking-schools, institutes for training servant-girls, barbers and chiropodists. You can find a school in Germany for teaching anything you want to know, and it is usually supported by the Government and free to all comers, or perhaps only a nominal tuition is charged. There is no reason why any person in this great Empire should be ignorant of the duties pertaining to the place he is required to occupy.

It is complained, however, that the Germans are more technical than practical; that they are spending too much time in developing theories without putting them into practice; that the learned doctors are discovering all sorts of new diseases without finding remedies for them; that the electricians are spending thousands of dollars in developing motors that will run 150 miles an hour, when nobody wants to travel at that speed, and neglecting the ordinary tramway-systems which are required for the convenience of the public. It is undoubtedly true that more discoveries in the different fields of science are made in Germany than in any other country. It is equally true, on the other hand, that German genius very seldom derives any great pecuniary profit from its discoveries and inventions. You never hear of a rich inventor, and comparatively few patents are granted — probably not as many in all Germany as in the State of Connecticut alone. The patent laws are very exacting. They require that an invention shall not only be unique, but that it shall be useful, in order to receive a monopoly from the Government.

One of the most interesting features of German educational life is the "industrial art-schools" in which young machinists are trained to become foremen and superintendents of factories. There are eleven such schools in the city of Berlin, and they opened the fall term with 2,512 pupils. They are situated in different parts of the city to serve the convenience of the working-classes, for whose benefit they are intended. There are two systems — one which furnishes instruction in every branch of mechanical industry, including designing, drawing, carving, moulding, modelling, surveying, engineering, chemistry, the use of instruments of precision and every phase of electrical science and mechanics, six hours a day for six days in the week. For this an annual fee of 100 marks ($25) is charged. In this school are representatives of the middle classes of society, who are not dependent upon their own earnings for support — the sons of manufacturers, merchants and skilled mechanics who earn good salaries.

The other system appeals to a much larger class of the population, and about 2,000 young men who are compelled to earn their own living take advantage of evening and Sunday instruction, that is given them for a nominal fee of 4 marks for the year for an average of four lessons a week, and six marks a year for an average of six lessons a week. Of course, this fee is merely formal, and is intended to appeal to the self-sespect of the pupil and remove the odor of charity. For two hours each evening and for four hours each Sunday instruction is given those whose circumstances compel them to work during the week-days. To enter, a candidate must have already gone through the common schools and acquired a solid foundation of general information. He must also pass an examination in mathematics, and must have served an apprenticeship of at least a year at some mechanical trade. Upon entering the school he has an option of seven or eight different departments, all of them dealing with the construction and operation of machinery, electric-motors, pumping-apparatus, locomotive or stationary engines, spinning, weaving, moulding, the manufacture and handling of all sorts of tools, forging, and every other form of mechanism. The instructors are practical men, and each student must follow a practical course. No time can be wasted in experimental work. Upon entering the school he must select his trade, and he will be educated thoroughly in that particular line of industry, so that he may not only be able to operate, but to design and construct, the machinery that pertains to it.

Many of the graduates of the schools of industrial art from their own inertia or from the pressure of circumstances fall back into the ranks of wage-earners, but more have the force of character to become captains of industry and superintend the work of others. — *Berlin Correspondence of the Chicago Record-Herald.*

THE VILLA BORGHESE COLLECTION.

CLAUDE PHILLIPS writes in the London *Daily Telegraph:* It is with a sigh of relief that the lovers of great art have learned that the Italian Chambers have passed the necessary credit for the acquisition by the nation of the great Borghese Collection now housed in the Villa Borghese — at the Government price, however, and not at that of the seller. The masterpiece of Titian's first period, which will always be popularly known as "Sacred and Profane Love," although an Austrian savant, Herr Franz Wickoff, has now ingeniously found for it the more appropriate and convincing title "Medea and Venus," will not then, after all, occupy a place in a Fifth-Avenue or a Boston palace, but will continue, as heretofore, to be in every sense one of the world's treasures, and a joy forever to the nations, since to them in the higher sense it belongs, and must ever belong. The removal from Rome of such a wonder of art as this would be more than a national, it would be an international, calamity; and to none more than to the Americans themselves, since they are among the most indefatigable, the most passionate pilgrims to the shrines of art all over the world. Now, as heretofore, the worshipper will be able to turn — for a moment's rest from delight — from Raphael, Titian and Correggio to Nature, and dream a moment in sweet forgetfulness of self as he looks through the tall pines of the Borghese Villa at the beautiful mountain-ranges which, environing Rome, crown her with a higher and more august beauty.

No private gallery can now vie with the Borghese Collection, though, like all those which were brought together in the past centuries, it contains, with the pearl of price, a fair substratum of inferior things, and even of downright rubbish. The Bridgewater Gallery comes next, and then the Liechtenstein Gallery at Vienna, and Dorchester House. It is the five or six world-famous canvases which have made the great fame of the Collection, although it is, even in other respects, full of interest to the student. Since Giovanni Morelli (Lermolieff) wrote his now famous work "*Die Galerien Borghese und Doria Pamfili in Rom*," this Gallery has been the favorite battle-ground of the critics. Signor Adolfo Venturi, following some years later with a *catalogue raisonné*, controverted a good many of Morelli's statements and opinions, and then was himself in turn challenged on some important points. The large "Deposition," painted by Raphael in 1507, for Atalanta Baglioni of Perugia, is the most ambitious work produced by the youthful Umbrian before he entered upon his great labors in Rome. It is at the same time the least successful, the most tormented, the most artificial. We find here a kind of staleness, of artificiality, very singular at this still early stage of the wonderful career — a premonition of the radical defects of conception which, quite apart from Giulio Romano's coarseness of interpretation, will later on so distressingly mar the "Transfiguration," which was once deemed the crowning achievement of Raphael's maturity. The "Sacred and Profane Love," consecrated by the passionate admiration of successive ages, need not here be further discussed; but opposite it hangs another Titian, "The Education of Cupid," painted some sixty years later in the life of the Master of Cadore, and yet at least as wonderful in freshness, in brilliancy, in unity of conception, in poetry. Titian is one of the few painters — it is only among the master-geniuses that they are found — whose interest both in heaven and earth increased as he went on, even to the very end. Then there is the sombre, passionate "St. Dominic" from the same brush, and belonging also to the late time — a magnificent portrait-study, to which, as yet, insufficient justice has been done.

No picture in the Gallery excites a sympathy more profound than the "Portrait of an Unknown Man," by Lorenzo Lotto. Sumptuously yet sombrely attired, still in the early prime of life, this *anonimo* fronts the spectator with a look of hopeless sadness, of mute appeal against destiny. One hand crushes down a heap of crimson roses, half faded, amidst which lurks, white and sinister, a little death's-head; the other is pressed in an involuntary gesture of pain to the side. What physical agony, corroding fair manhood in a body nobly fashioned, or what mortal despair, oppressing and crushing the spirit, does Lotto here seek to reveal, to interpret for the few, while he half-veils from the many the tragedy of the body or of the soul? We shall never know. And therein lies, perhaps, the great charm of the picture. Nothing, even in this magnificent *ensemble*, surpasses in grandeur of realism, in pathos, in splendor of aspect, the half-finished "St. John the Baptist in the Desert" of Paolo Veronese, who only on the rarest occasions — as in the "St. Sebastian" in the church of that name at Venice, in the wonderful "Pietà of the Hermitage" at St. Petersburg, in the "Pilgrims at Emmaus," and the small "Crucifixion" of the Louvre — attains to such heights as these. The "Danaë and the Golden Rain" of Correggio, one of the few art-treasures pacifically retaken by Italy from England, though it is by no means intact, shows at his highest point the master who sacrificed too much to an earthly, yet more than human, suavity and grace, to a harmony like that of faultless music, oversweet; not, indeed, a greater painter than he is in the unsurpassable "Jupiter and Antiope" of the Louvre, but a more supreme artist. He stands here in much the same relation to Raphael that Praxiteles is seen to hold if we compare him to Phidias. His is an art in which sensuousness is still spiritualized, in which genius justifies and transfigures conceptions already, in their very beauty, on the gentle incline which will ultimately lead to decadence.

NOTES AND CLIPPINGS

FIND OF COIN-FILLED ROMAN AMPHORÆ. — A discovery of ancient treasures is reported to have been made at Montalto in Liguria during the demolition of one of the most ancient churches in Italy. A small underground chamber was filled with objects of art dating back to the era of the Roman Empire. They consisted chiefly of silver amphoræ and vases, and were filled with gold and silver coins. — *Exchange.*

THE ARMS OF THE VENUS DE MILO. — A letter is published from the aged Admiral Reveillere, saying that M. Brest, a former French consul at Milo, who was influential in the acquisition of the Venus de Milo by France for the Louvre, once declared that he knew where the arms of the Venus were, but that no one should ever see them, because he thought the Government had given him too little credit for his share in the acquisition of the statue. Admiral Reveillere suggests that steps be taken to test the truth of M. Brest's statement concerning the arms. *Boston Transcript.*

PAINTING THE FIRTH OF FORTH BRIDGE. — The New York public has had the question of the painting of large bridges brought very forcibly and somewhat painfully to mind of late by the extraordinary disclosures of the report of the expert commission appointed by the District Attorney to examine the Brooklyn Bridge. In this connection a few facts regarding the system of painting adopted in the case of the largest and most important bridge in the world, the Forth Bridge, in Scotland, will be of interest. It seems that ever since this structure was opened for traffic, eleven years ago, the work of painting it has gone on without any interruption. A staff of about thirty-five men is employed on the work. They commence painting at the southern end of the structure (which, by the way, comprises two main spans of 1,710 feet and two shore spans of 700 feet), and the work proceeds daily, except on Sundays and in unusually stormy weather, until the northern end of the structure is reached. It takes three years to cover the full length of the bridge, which, in the cantilever portions alone, is about one mile in length. Hence it will be seen that this period of thirty-six months represents the useful life of the paint, since one coating is no sooner completed than the work is begun again. Already the huge structure is receiving its fourth coat. To enable the painters to conveniently reach every part of the structure the engineer in charge has devised a system of ladders and steam hoists. Where possible, ladders attached to the great struts and ties are made use of, but for reaching the loftiest portions of the cantilevers, which rise to a height of 360 feet above the piers, a series of permanent elevators have been installed. These are operated by means of steam winches, which are placed a little below the level of the roadway. In proximity to each elevator there is erected a house in which the paint is mixed. For painting the under side of the roadway permanent wire ropes are stretched along each side of the structure, from which the painters' platforms are suspended in such a way that they can be drawn along the rope very much after the manner of a cableway. Evidence of the throughness with which the work is done is seen in the fact that, so far, no portion of the bridge has shown any signs of decay or need for renewal. — *Scientific American.*

RAILWAY SUIT AGAINST A TRADE-UNION. — The trade-unionists are preparing vigorously to contest the claims of the Taff Vale Railway Company against the Amalgamated Society of Railway Servants. The amount claimed is about $125,000. This is the Company's estimate of the damage it suffered by the alleged conspiracy and combination of the Amalgamated Society in connection with the recent strike on the Taff Vale Railway. The House of Lords laid it down that a trades-union was liable for the action of its servants or members, and could be made answerable for such action in a court of law. Every trades-union throughout the country is watching the development of the case with the keenest interest. The union-leaders assert that the House of Lords' decision places the whole of their funds in jeopardy, and some unions are halting between the advisability of securing the bulk of their funds on the Continent, and of finding some means of putting their money safely away in England. — *N. Y. Tribune.*

THE DISCOLORATION OF BRICK. — A much-vexed question that has been discussed for many years by men of sound common-sense and great experience is that of the discoloration of brick. Some clays are a great deal more susceptible to discoloration than others, and even with the greatest care flashed brick is the result. In some instances kilns of tile are so badly flashed that the goods look like pieces of ware covered with Chinese characters. One of the chief causes of this discoloration or flashing is the setting of the tiles or brick too closely together to allow of the steam escaping. Again, when wood is used, even in small quantities, the color is likely to be poor. The steam that we have to contend with in the last stage of the burning is the principal cause of this, and on fine pressed-brick discoloration is much more noticed than on common brick. A superintendent of a large pressed-brick and tile works was at one time very much troubled with brick flashing, and did not find out the cause for a while, till one day he noticed that his men were raking out the ashpits and dousing them with cold water to cool them off. He thought that that perhaps was the source of the mischief, and stopped the practice, and, sure enough, he had no more trouble in that direction. Coal burnt too wet will sometimes produce the same result. The moisture in the atmosphere also exerts an influence in the same way. Of course we cannot control the weather, but we can see that our fuel is kept dry, and that our kilns are protected from the weather, and that goes a long way towards successful operation of the plant, and the cure of flashing. — *Stone Trades Journal.*

COPYRIGHT INFRINGEMENT. — It is decreed in the English Fine-Arts Copyright Act of 1862 that "if any person, not being the proprietor for the time being of copyright in any painting . . . shall, without the consent of such proprietor, repeat, copy, colorably imitate, or otherwise multiply for sale, or knowing that such repetition, copy or other imitation has been unlawfully made, shall sell . . . any copy . . . of the work . . . such person for every such offense shall forfeit £10." In the recent case of Hildesheimer *vs.* W. F. Faulkner, Ltd., which was an action brought to restrain infringement of the copyright by the defendants and to recover damages for the circulation of 1,012,600 copies of the plaintiff's pictures, it was decided by the trial court that the plaintiff was entitled to a penalty for each copy circulated, and that since this penalty must be some recognized actually existing sum in coin, the Court felt itself constrained to fix the penalty at a farthing for each copy. The defendants appealed. It was stated that the cost of producing a million copies of the picture was only about £100. The questions to be decided on appeal were: (1) Whether the order for the printing of a million copies constituted a million offences or only one offense. (2) Whether, if each copy constituted a separate offence, the penalty should be fixed at one farthing for each copy put in circulation, which would amount in the whole to £1,054 15*s.* 10*d.*, or whether it should be fixed at some smaller fraction of a penny for each copy. Lord Justice Rigby held that the Court was not bound to fix a sum made up of separate sums which would have been recovered if there had been a separate action for each offense. Lord Justice Collins, although holding that the defendants were technically within the law and that they had become liable in respect of a million copies, construed the statute to mean that a maximum and not a minimum penalty was inflicted. His Lordship could see no reason why in such a case the penalty should be limited in reference to a coin. In the present case the execution could only be for the aggregate sum. Lord Justice Romer, holding with his colleagues, found that if the statute were to be construed too literally the Court might be bound to award a sum which would obviously be far in excess of that which ought to be given, and the judgment would be doing that which the Act had carefully avoided doing, namely, fixing a minimum penalty. His Lordship could see no reason why, when the action was brought for a number of offences, a sum should not be given which, when divided by the number of offences, would give for each a fraction of the lowest coin of the realm. — *Scientific American.*

NOTES AND CLIPPINGS. 24

TOO late in the season to allow us to perfect our plans and make announcement earlier, we determined to make a change in the manner and method of publishing our International edition, and we now give notice that the change impends and will have effect in the second quarter of the year. The change consists simply in gathering the extra illustrations which constitute the International edition into four quarterly issues in place of their being, as now, scattered through thirteen weekly issues. The result will be that the subscriber to the International edition will receive each week a copy of the Regular edition and with each quarter a quarterly volume in which will be collected the gelatine and other International plates. That is, a subscriber will receive exactly what he now receives, but it will reach him in what, we believe, will be a more acceptable and agreeable form. Amongst other advantages incident to this condensation of matter is the fact that it will enable us to publish in the same issue all the plates in illustration of a given building, instead of being forced to let them dribble out, a few at a time, in four or five different weekly issues, as in the past. — *From our issue for Jan.* 4.

THE inaugural address of Mayor Collins of Boston calls attention to the imperative need of a new City Hall. The present building is crowded and inconvenient, and only accommodates a small portion of the necessary offices, so that the city is obliged to pay about thirty thousand dollars a year rent for offices in various outside buildings, some of them at a considerable distance, so that business is carried on in them at great inconvenience. As the sum annually paid for the rent of inconvenient outside accommodations would provide interest on at least a million dollars, while the ground occupied by the present City Hall, with the old Court House, now occupied for city offices, is of immense value for business purposes, and would probably meet with ready sale, the financial advantage of making a change is manifest. Where the new City Hall should be placed is not so evident. Mayor Collins thinks that the present location among the banks and lawyers' offices in the northern part of the city is not so convenient as a more central one would be, but he forbears to specify particularly any other. It is, however, well known that a situation either in the neighborhood of the Public Garden or of Copley Square is favored by the people who have paid most attention to the interests of the city. The old plan, of erecting a building on Beacon Hill, near the State House, seems to have been definitely abandoned. A few months ago, a carefully studied scheme was proposed for extending Arlington Street across the old Providence-Station grounds, and placing the new City Hall in the space between this new street and Park Square. This would provide adequate space, in a very accessible location, although it may be questioned whether such a building would not deserve a more conspicuous site than an open space behind the back gates of the Boylston-Street buildings. Artistically and, in some ways, practically, the best location now available would probably be the Art-Museum lot, on Copley Square. The cost of this lot, which contains more than two acres, and borders on four streets, would probably not be excessive, while a building on it would show to the fullest advantage in the company of the Public Library, Trinity Church, and the other splendid structures which already adorn Copley Square, or will soon do so. As lines of electric cars from nearly every part of the city and suburbs pass through Dartmouth Street, Boylston Street or Huntington Avenue, this lot would be as accessible as that on Arlington Street. Either lot would, without question, form an admirable site for the structure, and, while architects, who naturally like to see a fine building placed in a conspicuous location, would probably favor Copley Square, a City Hall on the extension of Arlington Street could, by judicious management of the surroundings, be made imposing and beautiful.

THE profession will hear with great regret of the death, after a long illness, of Mr. Edward Clark, Architect of the Capitol at Washington. Mr. Clark was born in Philadelphia in 1822, and was assistant to Dr. Thomas U. Walter when the latter was engaged in the construction of the wings and dome of the Capitol from his own designs. On Dr. Walter's resignation of his position, in 1865, Mr. Clark succeeded him, and has ever since had charge of the building. As an available expert of high reputation, he was called upon to carry out many other duties in connection with the Government building work in Washington, and served on many commissions, those for the completion of the Washington Monument and the construction of the Congressional Library among others. He had long been a member of the American Institute of Architects, as well as of various other artistic and scientific bodies, and was highly esteemed by his associates, not only for his professional skill, but for his uniform courtesy and kindness to all with whom he was brought in contact.

THE President of the Boston Manufacturers' Mutual Fire Insurance Company, 31 Milk Street, Boston, asks information from architects in regard to their experience of the corrosion of structural steel under various circumstances. He says that it has been observed in England that concretes made with "breeze," or what we should call cinders, are often very destructive to iron and steel, and that, within his own knowledge, beams imbedded in concrete in foundations have been found to corrode very rapidly, in consequence, apparently, of some corrosive qualities of the concrete surrounding them. It is hardly necessary to say that these observations are of the very greatest importance to every one connected with the art of building. Many millions of dollars are invested every year in this country in buildings supported solely by columns of steel, surrounded by masonry set in cement, with, in the best buildings, a grouting of cement between the masonry and the metal. Experience has shown that corrosion, if it occurs at all, is likely to be most serious in the portions of the frame nearest the ground, for the reason, probably, that the moisture which all masonry contains, or absorbs from heavy rains, sinks by gravitation into the bottom of the mass; and it is precisely at this point that the loads are greatest, and failure of the metal would be most disastrous. Most engineers and architects in this country believe that if the metal is thoroughly cased with masonry in cement, or cement-concrete, in contact with it, there is almost no limit to its duration. Of course, no architect or engineer of experience would leave structural members of iron or steel in contact with plaster-of-Paris, which is well known to corrode the metal rapidly; and very recently it has been shown that paint, on iron intended to be buried in concrete or masonry, is of doubtful utility, if, indeed, it is not seriously injurious; but we do not think that any case has been made known to the profession, otherwise than as mentioned by Mr. Atkinson, where the corrosion of structural iron could be directly traced to cement-concrete in contact with it. It is possible that the cement used for making concrete in England may have contained ground slag, which often contains sulphur, and might, perhaps, develop a corrosive action on iron in consequence; but it is difficult to understand how the English "breeze," unless it is something very different from our coal cinders, could contain anything corrosive, or how, if it did, it could exert any material action on the metal through the pores

Entered at the Post-Office at Boston as second-class matter

of the concrete of which it formed the aggregate. So far as our materials are concerned, we believe that there is little to fear from acid concrete or cement, and still less from acid cinders, but it is not impossible that the coating of paint so universally used may be more injurious than has been supposed. In a steel-frame building which was altered some years ago in New York, the first-story exterior columns were found deeply corroded, from some cause not explained, and it would be well worth while, in the case of similar alterations, to have the condition of the metal thoroughly examined; or even, where such immense sums are at stake, without insurance, as in the modern office-buildings, to lay bare, occasionally, the lower portion of one or two of the important supports of the frame for inspection. If any of our readers have any experience in the matter, it would be particularly desirable to make it known just now, when it will be of assistance in planning the thorough tests which Mr. Atkinson hopes to have made, primarily for the information of his insurance company, but incidentally for the advantage of the whole community.

THE attention of architects who have five thousand dollars that they are anxious to get rid of is invited to a proposition of the Milwaukee Commissioners of Public Works, who advertise for competitive plans for a school-house, to contain twenty class-rooms, assembly-hall, teachers' rooms and so on; to have approved systems of ventilation, heating and sanitation, and to cost complete, including fees of architect and inspector, not more than seventy-five thousand dollars. As this is about half the usual cost of school-buildings of these dimensions the Commissioners very prudently make sure that the architect shall contribute to the expense by requiring that he shall furnish an approved bond for five thousand dollars, guaranteeing the erection of the building complete, including the fees mentioned, for the specified sum; and as a reward for the ingenuity and generosity involved in such an undertaking, they promise the fortunate professional man "the usual compensation allowed by the city for such work," that is, four per cent on the first ten thousand dollars, three and one-half per cent on the second ten thousand, and three per cent on the remainder.

THE management of the St. Louis Exposition announce that an international competition is to be held for a design for a symbol, or emblem, to be used on the seals, stationery and other "publicity material" connected with the Exposition. No rules are laid down as to the lettering, sentiment, size or style of the design. It is only stipulated that it shall be symbolical of the historical event commemorated by the Exposition: the purchase by the United States, in the year 1803, of the Louisiana territory from France, by which, for the sum of fifteen million dollars, the United States secured the control of the Mississippi Valley. Under the terms of the competition, eight sculptors are to be selected, who are to be paid two hundred and fifty dollars each for their designs, but all artists are admitted to submit designs, which, it is promised, shall be judged on an equality with the others, by a jury of national reputation, and the author of the design placed first is to receive a prize of twenty-five hundred dollars. Six months is allowed for the preparation of the designs, but, as the circular is not dated, we are unable to say when the six months will expire, and we have no information as to the place at which competing designs are to be delivered. Probably these details will be given later. Meanwhile, it may be useful to know that more than two hundred volunteer designs have already been submitted, using such materials as a map of the Louisiana Purchase; portraits of Thomas Jefferson and Napoleon Bonaparte; the fleur-de-lis, the eagle and the Napoleonic N; the intertwined flags and arms of France, Spain and the United States; the Mississippi Bridge, and other devices, none of which were considered suitable; so that competitors will do well to avoid these combinations.

L'ARCHITECTURE quotes from the *Bulletin* of the French Société des Architectes Diplômés an interesting article on a matter of professional etiquette. It seems that a member of the Society, in considering a matter of employment to carry out some municipal works, was told by the town officials that a brother architect had guaranteed, in a similar case, if the cost of the building carried out from his designs should exceed the contract price, to pay the excess out of his own pocket up to a certain limit, the inference being that, if he wanted to secure the commission, he must make a similar promise. The member had doubts of the propriety of such a course, and applied for counsel to the officers of the Society. He received two replies, one from M. Louis Bonnier, President of the Society, who advised him "very politely, but very firmly" to decline compliance with the suggestion; and the other from M. Guadet, perhaps the most distinguished of French architects, who, in a letter which was shown to the officials of the municipality, and which led them to recede from their position, said that an architect could not, and should not, agree with any client to pay the excess of cost of a building over the contract price, for the reason, among others, that the architect does not participate in the contractor's profits, and that an agreement to assume all, or a part, of the losses of an undertaking, without a provision for sharing in the profits, is forbidden by the French law. M. Guadet observed also that a contract of the kind proposed, between an architect and his client, even supposing that it could be legally made or enforced, would destroy the position of the architect as the guardian of his client's interests by creating for him an interest directly opposed to that of his client, and inciting him to admit, for the sake of saving his own pocket, economies which it would be his professional duty not to tolerate; and he pointed out, as we have ourselves done in a similar case, that such a contract, even if it were legal, would, in practice, be absolutely worthless as a protection to the client, for the reason that the slightest modification from the plans and specifications, made at the desire or request of the client, after they had once been accepted, would release the architect entirely from his guaranty; and, as M. Guadet says, no building was ever carried out without such modifications. In this country sharp town officials, who probably understand better than the architects the illegality and futility of such contracts, usually put their proposition in the form of a demand that the architect shall deposit a certified check or a sum in cash as a guaranty. We do not know that we ever heard of an architect's complying with the demand; but the object of making it is, evidently, to enable a municipality, by setting up absurd claims in place of those which, in practice, never have a real or legal foundation, to compel the architect to engage in a long and costly lawsuit to get his money back; and, in that way, to induce him, as an alternative, to submit to a "compromise," or, in other words, to pure and simple extortion.

M. GUADET speaks of another point which has been much discussed in this country, and in regard to which professional opinion, as well as professional practice, varies. He mentions, in a postscript to his letter, that an agreement is sometimes made between architects and municipalities, or other important clients, that the architect shall not receive a commission on any excess of cost of the building over the contract price, unless it shall appear that the excess was due to changes or increase in the amount of work made at the desire of the client. Such an agreement he considers legal and unobjectionable; and, although it opens the way to differences of opinion as to what extras, if any are ordered, should be added to the sum on which the commission is reckoned, it does not act as an inducement to the architect to wink at violations of the contract for the purpose of reducing the cost; and a skilful architect and a reasonable client rarely find any difficulty in settling their accounts.

THE citizens of Cleveland, Ohio, have in contemplation a scheme which promises great results. It happens that a new post-office, a court-house, and some other public buildings are to be erected in the city within a short time, and the suggestion was made that the buildings should be so arranged as to improve the effect of all by suitable grouping. The suggestion was received with a favor which is most creditable to the intelligence of the city, and the Federal Government signified its willingness to aid the scheme by taking land for the post-office in such a situation, within reasonable limits, as might be best adapted to the general plan. In general, the scheme proposed is to form a wide street, running north and south, on either side of which the public buildings are to be arranged, the cross streets accommodating the private structures which always crowd into the neighborhood of the public ones. Nothing could be either more simple or more convenient than this plan, and it is much to be hoped that it may be carried out. We should like to see the central "boulevard" laid out with occasional deviations from perfect straightness and of varying width, believing that the beauty of effect of the buildings and of the street could be enormously increased in that way; but it is, perhaps, too much to hope that any American city engineer would consent to such an innovation.

NOTES ON IRON AND STEEL CONSTRUCTION.[1]—II.

THE principal structural members in any framed construction are the beam, or girder, and column, and since all the rules and formulas for determining the strength of such members are based upon values which are called the properties of the section, it is necessary to understand the calculations and methods for finding these values and their application, in the design of the structural members.

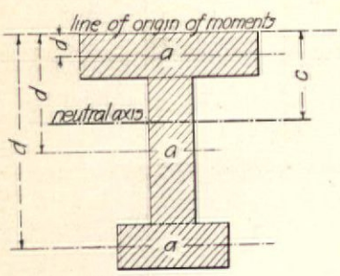

Fig. 1.

The two values of interest to the structural-engineer are the moment-of-inertia, and the radius of gyration. These terms are more or less meaningless and are simply names given to the values of a structural section in resisting flexure, and failure through flexure from compression, and are the only values by which one section can be compared with another in its ability to withstand the stresses to which the members are subjected.

In determining the moment-of-inertia, and the radius of gyration is found from this value, the determination of the moments of the individual fibres, or infinitely small areas of the section about a certain line, is the principle of the calculation. This line is called the neutral axis, and is considered as passing through the centre-of-gravity of the section, and is always taken at right angles, or perpendicular to the direction of the load action.

When the section is symmetrical — that is, equally proportioned on each side of a centre line, the neutral axis is coincident with the centre line, and requires no determination. When however, the section is not symmetrical, there are three methods which may be employed in the determination of the position of the neutral axis; they are: the mechanical, the mathematical, and the graphical. Where only approximate results are required and the section is somewhat complex, the mechanical method is sufficiently accurate for all practical purposes. This method has been recommended by Trantwine and others, and consists of cutting out an accurate scale pattern of the section, from an even thickness of cardboard, and balancing it on a knife-blade so that the blade is perpendicular to the direction of the load, in a beam section, or, in the case of a column section, usually perpendicular to the least diameter of the column section. A line marked where the knife-blade rests when the pattern is balanced is the position of the neutral axis.

The mathematical method of determining the neutral axis is quite simple, and consists of multiplying each simple elementary area by the distance between its centre-of-gravity and a line without the figure, called the line of origin of moments, and dividing the sum of these products by the entire area of the section. The result so obtained will be the distance that the neutral axis is located from the line of origin of moments. This distance is usually designated as the distance *c*. The algebraic formula which expresses this rule is clearly understood when reference is made to the preceding sketch, designated as Figure 1. In the formula which may be written thus:

$$c = \frac{\Sigma a d}{A}$$

c equals the distance which it is desirable to obtain, *a* equals the area of each simple elementary section, *d* the distance from the centre-of-gravity of each simple elementary section to the line of origin of moments, while Σ signifies, as usual, the summation of the anteceding quantities. The application of this formula may readily be understood from the following: —

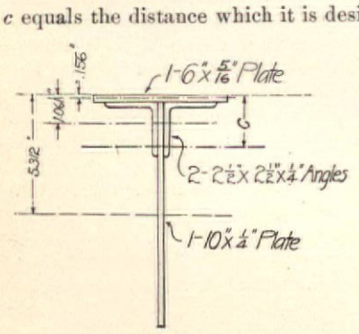

Fig. 2.

Example. — In the section marked Figure 2, what is the distance *c* from the line of origin of moments?

Solution: —

Area *a* of	6″ × 5/16″ plate.....	= 1.872	square inches.
Area *a* of two	2½″ × 2½″ × ¼″ angles	= 2.38	" "
Area *a* of	10″ × ¼″ plate.....	= 2.50	" "
	Total area.....	= 6.752 = *A*.	

The *a d* for each elementary section equals: —

Flange plate	1.872 ×	.156 =	.292
Flange angles	2.38 ×	1.062 =	2.527
Web plate	2.50 ×	5.312 =	13.280
And the summation.....		=	16.099

Upon substituting these values just found in the formula $c = \frac{\Sigma a d}{A}$ it becomes $c = \frac{16.099}{6.752}$ or 2.38, which is the distance in inches from the outside fibre of the flange-plate to the neutral axis.

The graphical method of determining the neutral axis or the position of a line passing through the centre-of-gravity of a section is readily applied, and is preferred by many on account of its simplicity and reliability.

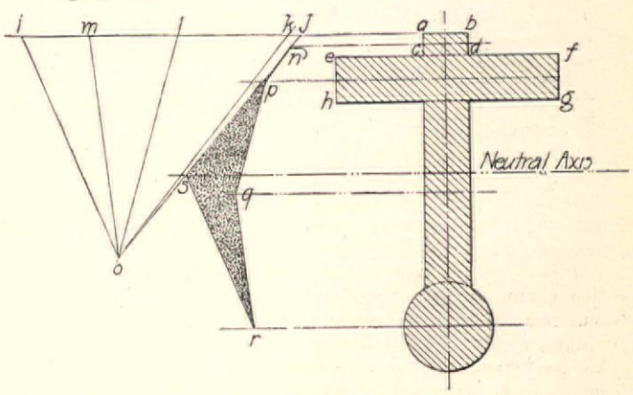

Fig. 3.

Figure 3 shows the section of a cast-iron rib, which may be a cast-iron rafter member in a skylight, or any other structural member. The problem, to determine graphically the position of the neutral axis of this section, may be proceeded with as follows: Through the centre-of-gravity which may be determined by inspection of each simple elementary section, such as *a b c d*, or *e f g h*, draw horizontal lines as shown in Figure 3. From the outside line of the section draw any indefinite horizontal line, as *a i*, and upon this line lay off spaces to scale which represent the areas of the respective elementary figures composing the section. For instance, the area of *a b c d* equals one-half of a square inch, and the area of *e f g h* equals 5 square inches; if the selected scale has been such that one-half of one square inch equals one-half inch in length, then the distances *j k*, *k l*, which represent the areas of *a b c d* and *e f g h*, will be one-fourth and 2½ inches respectively. Having laid off also the distances *l m* and *m i*, equal respectively to the areas of the web and bulb of the section, proceed with the figure by drawing to any point outside the horizontal line, as *o*, lines from the point *j k l m* and *i* as previously laid off. From *n* draw a line *n p* parallel to *k o*, and from *p* draw a line *p q* parallel to *l o*; likewise from *q* draw a line parallel to *m o*, and from the last point, *r*, just found, draw the line *r s* back until it intersects *j o* at *s*. A horizontal line drawn through the point *s* will coincide with the neutral axis and will pass through the centre-of-gravity of the figure. The method just described is quite useful when it is necessary to deal with a very irregular figure, and is a part of the graphical method for determining the moment-of-inertia of complicated sections which will be described directly.

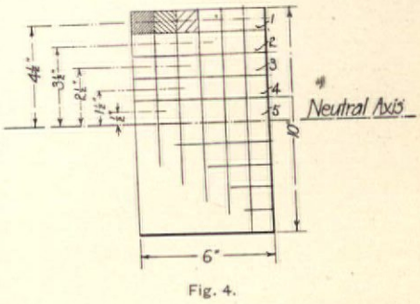

Fig. 4.

The principal end in view in determining the position of the neutral axis is in order to be able to conveniently calculate the moment-of-inertia. This value, the moment-of-inertia, may be found for any section by dividing that section into as nearly

[1] Continued from No. 1358, page 5.

as possible unit areas, and finding the sum of the products of each elementary unit area by the square of the distance from its centre-of-gravity to the neutral axis. In applying this rule take, for instance, the following problem, which consists of the solution for the determination of the moment-of-inertia of the rectangular section shown in Figure 4.

The outside elementary or unit areas marked 1 have a value equal to $4.5^2 \times 6$ (their number), or 181.50; there are, however, an equal number on the other side of the neutral axis, and, consequently, the rectangular section under consideration has twelve elementary areas possessing the same value when considered in reference to their distance from the neutral axis; in fact, the elementary or unit areas are here considered as one inch square, though they may as well have been regarded as infinitely small in area, and thus represent the fibres of the material of which the beam section is composed. If such a calculation were possible, accurate results would be obtained by this method of calculation. But to continue the solution of the problem: there exists, besides the twelve outside elementary areas marked 1, the second set, and likewise the third, so that the entire value, or the moment-of-inertia of the section, may be calculated and tabulated as follows: —

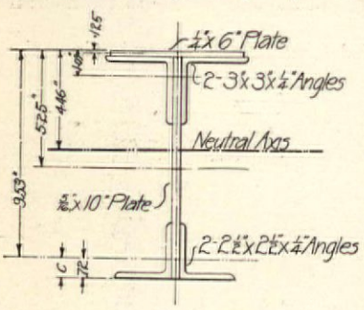

Fig. 5.

Fibres or areas marked 1 $= 12 \times 4\frac{1}{2}^2 = 243.00$
Fibres or areas marked 2 $= 12 \times 3\frac{1}{2}^2 = 147.00$
Fibres or areas marked 3 $= 12 \times 2\frac{1}{2}^2 = 75.00$
Fibres or areas marked 4 $= 12 \times 1\frac{1}{2}^2 = 27.00$
Fibres or areas marked 5 $= 12 \times \frac{1}{2}^2 = 3.00$
Total ..... $= 495.00$

This value, then, represents the moment-of-inertia for the rectangular section designated in Figure 4, and is sufficiently accurate for all practical purposes.

This method just described is useful from the fact that it can be applied to any section, no matter how irregular, and all that need be done is to draw the section to scale and divide it into elementary areas as accurately as possible, and proceed with the calculation as explained.

Where the section is a simple geometrical figure, such as a rectangle, circle, triangle, or where it is a combination of several such elementary sections, it would be somewhat tedious to make an extensive calculation like that just explained. Since, therefore, these simple elementary sections are used almost exclusively in construction, formulas which will express the value of the moment-of-inertia for the different sections have been deduced by higher mathematics, and are included in the usual memoranda, or data, of the structural-engineer, as follows: —

PROPERTIES OF USUAL SECTIONS IN CAST-IRON — CORRECT VALUES.

A = total net area of section. I = moment-of-inertia.

Section.	Moment-of-inertia.	Section modulus.	Least radius of gyration.	Distance from lower edge of section to neutral axis.
	$\frac{b\,d^3}{12}$	$\frac{b\,d^2}{6}$	$\frac{b^2}{12}$	$\frac{d}{2}$
	$\frac{a^4-b^4}{12}$	$\frac{a^4-b^4}{6\,b}$	$\sqrt{\frac{a^2+b^2}{12}}$	$\frac{a}{2}$
	$\frac{A\,d^2}{16}$	$\frac{A\,d}{8}$	$\frac{d}{2}$	$\frac{d}{4}$
	$.0491\,(D^4-d^4)$	$.0982\,\frac{D^4-d^4}{D}$	$\frac{D}{2}$	$\frac{1}{4}\sqrt{(D^2-d^2)}$
	$\frac{b'n^3+bn'^3-(b-b')\,a^3}{3}$	$\frac{I}{c}$	$\frac{I}{A}$	
	$\frac{bh^3-2\,b'\,h^3}{12}$	$\frac{2\,I}{h}$	$\frac{I}{A}$	
	$\frac{h^4}{12}$	$.1178\,h^3$	$\frac{h}{3.46}$	

PROPERTIES OF USUAL ROLLED-STEEL SECTIONS. — APPROXIMATE VALUES.

A = total net area of section. For minimum sections.

Section.	Moment-of-inertia.	Section modulus.	Least radius of gyration	Distance from lower edge of section to neutral axis.
	$\frac{A\,d^2}{6.1}$	$\frac{A\,d}{3}$	$\frac{b}{5.2}$	$\frac{d}{2}$
	$\frac{A\,d^2}{6.73}$	$\frac{A\,d}{3.3}$	$\frac{b}{3.56}$	$\frac{d}{2}$
	$\frac{A\,d^2}{10.4}$	$\frac{A\,d}{7.4}$	$\frac{d}{3.5}$	$\frac{d}{5}$
	$\frac{A\,d^2}{9.9}$	$\frac{A\,d}{6.7}$	$\frac{d\,b}{2.6\,(d+b)}$	$\frac{d}{3.1}$
	$\frac{A\,d^2}{10.9}$	$\frac{A\,d}{6.7}$	$\frac{b}{4.66}$	$\frac{d}{3.3}$
	$\frac{A\,d^2}{19}$	$\frac{A\,d}{7.6}$	$\frac{d}{4.74}$	$\frac{d}{2}$

While the first of these tables is accurate, the second is only approximate. That this second table of formulas cannot be exact is due to the fact that a certain depth and weight, of beam or channel, may have the metal in its section distributed in several ways, — for instance: the beam may have the bulk of the material in its section located in its web, while another beam of the same depth and weight per foot, maybe, will have the greater proportion of the material located in the flanges.

In the formulas for determining the transverse strength of beams is introduced a value derived from the moment-of-inertia, and it is usually called the section modulus, though it has been called, rather erroneously, it would seem, resisting moment or moment of resisting, and, also, resisting inches.

This value, the section modulus, is found by dividing the moment-of-inertia of the section by the greatest distance from the neutral axis to the outside fibre of the section. If the section modulus is represented by Q, and the moment-of-inertia by I, with the distance from the centre-of-gravity or neutral axis of the section by c, the formula for the value is $Q = \frac{I}{c}$. This value Q is necessary in determining the resistance to transverse strength of beams and built-up sections, and, consequently, it is often necessary to determine the moment-of-inertia of compound sections in order to ascertain their section modulus, and, subsequently, strength of the beam represented by the section.

Since nearly all compound structural sections composed of rolled steel are made up of several rectangular sections, or of rolled sections whose properties are known, the moment-of-inertia of such sections is readily obtained by observing the following:

Rule: — The moment-of-inertia of any compound section is equal to the sum of the products of each elementary rectangular figure composing the section, by the square of the individual distance between its centre-of-gravity and the neutral axis of the entire section, plus the moment-of-inertia of each elementary rectangular figure.

This rule is more concisely stated in the formula $I = \Sigma\, a\, d^2 + i$, in which Σ, or Sigma, represents, as before stated, the summation of the several values found by applying the succeeding formula to the several elementary rectangular sections; a equals the elementary area; I equals the distance from the centre-of-gravity of the elementary area in question to the neutral axis of the section, and i equals the moment-of-inertia of the elementary area or figure under consideration.

In applying the above rule and formula, let us consider the moment-of-inertia for the section shown in Figure 5.

It is first necessary to find the location of the neutral axis, which is accomplished by applying the formula previously given: $c = \frac{\Sigma\, a\, d}{A}$ and making the calculations as follows: —

Flange-plate ..... $\frac{1}{4}'' \times 6''$; $a\,d = 1.5 \times .125 = 1.875$
Flange angles ..... $3'' \times 3'' \times \frac{1}{4}''$; $a\,d = 2 \times 1.44 \times 1.09 = 3.139$
Web-plate ..... $\frac{5}{16}'' \times 10''$; $a\,d = 3.12 \times 5.25 = 16.380$
Lower flange angles $2\frac{1}{2}'' \times 2\frac{1}{2}'' \times \frac{1}{4}''$; $a\,d = 2 \times 1.19 \times 9.53 = 22.681$
The sum of $a\,d$ for each elementary section..... $= 44.075$

The total area of the entire section equals 9.88, and, consequently, distance c equals $44.075 \div 9.88$, or 4.46 inches from the

line $a\,b$, or origin of moments. The section redrawn, with the neutral axis located and the dimensions given, necessary in order to calculate the moment-of-inertia, is shown in Figure 6, and the calculation may proceed as follows: —

$$I = \Sigma\, a\, d^2 + i$$

Then $a\,d^2 + i$ for

Flange plate.....	$\frac{1}{4}'' \times 6''$	$= 1.5 \times 4.335^2 +$	$.0078 =$	28.19
Flange angles.....	$3'' \times 3'' \times \frac{1}{4}''$	$= 2 \times 1.44 \times 3.37^2 +$	$2.48 =$	35.16
Web plate.....	$\frac{5}{16}'' \times 10''$	$= 3.12 \times .79^2 +$	$26.04 =$	26.23
Lower flange angles	$2\frac{1}{2}'' \times 2\frac{1}{2}'' \times \frac{1}{4}''$	$= 2 \times 1.19 \times 5.07^2 +$	$1.40 =$	62.56
		Total, or $\Sigma\, a\, d^2 + i =$		152.14

Which result is the value for the moment-of-inertia for the built-up section. The section modulus can be found by dividing the value, 152.14, just found, by the distance from the neutral axis to farthest outside fibre, which is 5.79 inches. Making this division, the section modulus for the section shown in Figure 5 and 6 is found to be 26.3.

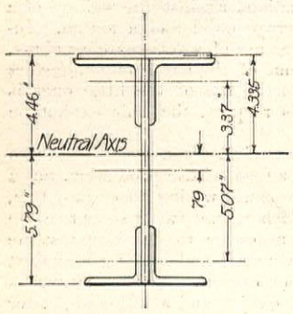

Fig. 6.

In making the calculations for the properties of compound sections composed of rolled-steel shapes, there are several values that it is necessary to know, and they are the moment-of-inertia of the rolled section and the distance from their outside fibres to the neutral axis. These values can be figured by the methods and formulas given, or they may be obtained from the tables printed by the several steel mills and issued in the form of a handbook to their patrons.

In making the calculations for the section shown in Figure 5 it will be noticed that the distance c for the angles had to be obtained in order to obtain the distance d used in the preceding calculation, and also that the moment-of-inertia for each section, or i, appears in the notation of the calculation.

The following tables, which are compiled from the "*Passaic Rolling Mills Pocket Book*," give the values used in the calculation, and will be found useful in determining the properties of any compound section composed of angles or plate, and in the design of any structure which will be treated of hereafter:

MOMENT-OF-INERTIA OF RECTANGULAR SECTIONS. — AXIS AT RIGHT-ANGLES TO GREATEST DIMENSION OF SECTION.

Depth in inches.	Width of rectangle in inches.						
	$\frac{1}{4}$	$\frac{3}{8}$	$\frac{1}{2}$	$\frac{5}{8}$	$\frac{3}{4}$	$\frac{7}{8}$	1
6	4.50	6.75	9.00	11.25	13.50	15.75	18.00
7	7.15	10.72	14.29	17.86	21.44	25 01	28.58

Every practical consideration in connection with the properties of sections has been explained, except the graphical method of determining the moment-of-inertia. The principle of the method is the same as that to determine the neutral axis, and consists of dividing the area of the figure included between the points J, n, p, q, r, s, as shown in Figure 3, by the total area of the section of the member.

M. M. Sloan.

[To be continued.]

THE PALACE OF THE QUEEN MOTHER, ROME.

AMONG the many buildings torn down in the improvement of Rome was the palace of Prince Buoncompagni-Piombino, which was removed for the enlargement of the Piazza Colonna.

The need of a new family residence led to the erection of this entirely modern palace, which was built under the direction of the designing architect, Gaetano Koch, who, on this occasion, has shown his great merit as designer and artist, and has erected a palace which compares most favorably with the older Roman palaces, from which he has drawn his inspiration, and one well befitting a princely residence.

Situated on the higher level of the Quirinal Hill, on the site of the Villa Ludovisi, it is surrounded by its extensive and lovely gardens containing two villas, one of recent construction, erected by Koch. The palace is artistically placed at the curve of Via Veneto, a large, handsome road leading up from the Piazza Barberini to the gardens of the Villa Borghese, and, while it commands a fine outlook, it also presents itself to the view in a most advantageous and striking manner.

The facade is in the sixteenth-century style and recalls to mind the Farnese Palace: in the centre is the main entrance, composed of three large arches which permit the passage of carriages into the spacious *atrio;* from this access is had to the vestibule leading to the grand stairway, which has been made a chief feature in the building, and here Koch has freely indulged his artistic feeling; at the foot of this stairway he has placed the well-known group by Bernini, "Il Ratto di Proserpina."

This statue formed a part of the Ludovisi Museum, formerly held in the Villa Ludovisi. The Palazzo Piombino, which took its place, was constructed not merely for a residence, but also to receive this valuable collection belonging to the family Buoncompagni-Piombino, and nothing was spared to give these precious works of art a worthy setting.

Koch, in his arrangement of the grand stairway and the connecting gallery, has fully complied with the requirements. This gallery of imposing proportions runs along the rear of the ball-room, dining-room, drawing-room, and bedrooms, which occupy the entire front of the second floor, and gives access to the same. In the decoration of the gallery he has made use of the handsome marbles, columns, tapestries and paintings of the Villa Ludovisi, and has most artfully combined these with the modern decorations.

After the assassination of Humbert I, the Queen left the royal palace of the Quirinal, but desiring to continue her residence in Rome. After diligent search the Palazzo Piombino was found to be the best adapted for a royal residence, and the whole property was purchased by the House of Savoy for an approximate sum of $600,000. Queen Margherita has occupied it since December, 1900; her private apartment consists of five rooms on the second floor contiguous to the large salon in the centre.

The two villas, which were intended as residences for the children of Prince Piombino, are now destined for the use of the members of the immediate family of Queen Margherita during their presence at Rome. No changes were made in the buildings beyond necessary internal renovations, but the valuable collections contained in the palace has been purchased by the Government and will be removed to the National Museum in Rome, where they may be admired by the public, for whom they have been always inaccessible.

This palace, under the auspices of Queen Margherita, will become a centre for the encouragement of art, literature and charity; it is especially in charities that the Queen Dowager interests herself, and recently she purchased a near-lying bit of property which has been converted into an asylum for children whose fathers have met with violent death; this is being connected by means of an underground passage with the palace and will be under the personal supervision of Queen Margherita. Thus, surrounding herself with charitable works, this unfortunate Queen has formed for herself, in the palace that we have described, a peaceful abode, where in seeking to alleviate the misfortunes of others she may find consolation for her own great sorrow.

JAMES GILMORE.

COMMON CAUSES OF FIRES.

SPEAKING of the fires which occurred in this country in 1900, an insurance paper, *The Chronicle*, recently made two striking statements. Very nearly half of them — 46.24 per cent, to be exact — were in dwellings, and 90 per cent of these were due to preventable causes. Almost the only unavoidable fires are those resulting from being situated next to another building which is ablaze. Practically everything else in the way of a conflagration *The Chronicle* attributes to some form of carelessness.

The defective flue is credited with making more mischief than any other one cause. Soot accumulates there by degrees without doing harm until peculiar conditions of draught, attended by chemical changes, perhaps, set the chimney on fire. If the flue is properly built no harm will ensue, but bad construction is liable to be followed by disaster at such times. Whether one rents or buys a house in which stoves, ranges, grates and furnaces are to be used, he should have his chimneys inspected by a competent and disinterested builder, to make sure that they are as they should be. *The Chronicle* insists that they should be of the best brick, preferably double-walled, or else lined with terra-cotta or fire-clay. The very best mortar should be used, and the bricks painted inside as well as out. This is better than plastering the whole inner surface, because smoke tends to disintegrate the coating. The slightest perforation in the chimney is likely to enable a spark to escape, or at least to invite the lodgment of soot.

A chimney ought to rest on the ground or have six courses of brick at the bottom in case it is supported by a timber foundation. A flue should never be so built on joists that a stove-pipe can enter it vertically. Cement or vitrified pipes ought not to be used as flues, and no woodwork should be allowed to come within 2 inches of the chimney.

In erecting stove-pipe, each joint should open back toward the stove. In that way the escape of sparks into the room will be prevented. Pipe should be inspected occasionally to see whether moisture has corroded it. When it passes through a ceiling or floor, it should be surrounded by a double-walled tin collar, with at least an inch of space between the two sheets of metal, and the collar should be of ample length. Unused stove-pipe holes in a chimney should be stopped with metal.

One of the most incendiary combinations against the welfare of a household is that effected by the average child and a match. Insurance-men are constantly advising the use of safety-matches alone, and the habit of keeping even these out of the hands of youngsters is strongly commended. Inasmuch as the life of the little ones is hazarded by too great license in this respect, the rule cannot be enforced too rigidly.

Gas-jets, when near woodwork or curtains, are a constant source of danger. Glass chimneys or globes afford a little protection, but a wire cage is much better. And if one is not willing to employ this, he would do well to adopt a fixture which cannot swing so as to come in contact with draperies. It is also necessary to guard against the possibility of a puff of wind catching a curtain and blowing it against the jet. Many fatal fires have thus been caused. At least 20 inches of space should intervene between a gas-jet and a lath-and-plaster ceiling. Otherwise there should be a metal screen, itself fully an inch from the ceiling.

There are people ignorant or careless enough to-day to need warning not to fill or trim kerosene lamps at night. A still larger proportion of the population is unaware of the risk of letting the oil get very low in the reservoir and of turning the wick down without entirely extinguishing the flame. The former practice is conducive to the generation of explosive gases in the lamp, and the latter overheats the burner. Of course, so long as one consumes high-grade oil he is safe, even under these circumstances. But where low-grade oils are burned there is a chance that the naphtha or gasolene which they contain will make trouble. The same precautions should be observed with oil-stoves as oil-lamps.

Regarding the furnace, *The Chronicle* offers the following suggestions: —

Place it on a solid foundation of brick or stone. Have stone, brick or metal not less than 36 inches wide in front of the ash-pit. The dome of the furnace should not be less than 18 inches from the unprotected woodwork above. The smoke-pipe should not be less than 12 and the hot-air flues not less than 8 or 10 inches from the side walls of combustible material. The hot-air flues should be constructed of IX bright tin, and they should be double where they pass through wood or lath-and-plaster materials. There should be an air-space of at least $\frac{1}{2}$ inch between the inner and outer flues. Set the register in soapstone frames not less than 2 inches wide and well bedded in plaster-of-Paris. Make register-boxes of IX bright tin, if they pass through floors. Have the joist and floor timbers framed around them so as to leave an air-space from 2 to 3 inches wide, and cover the exposed woodwork with tin on all sides.

Use a metal air-trunk or inlet, with a wire net or grating at its outer opening. Wooden air-trunks are exceedingly dangerous, for at some time a reversal of the draught is likely to occur and carry sparks into the wooden shaft. Have an expert inspect your furnace before lighting and see that the lining has not been burned through. Keep at least one of the registers open all the time.

THE ACTION OF WIND AND WATER ON SEA-CLIFFS.

BY the sea precipices of the West the foam-fringe and the winds are the greatest of all natural forces. These Atlantic winds, wave-compelling, rock-destroying, drive the hosts of ocean, rank behind rank, to the onset, and search from foot to crest each face and crevice of the towering cliffs. The foam and surge, the bondslaves of the winds, the heavy and light artillery of the ocean bands, are the visible agents of destruction, and on the Cornish coast develop a power so awful, with a display of form and motion so sublime, that the imagination could never picture one-half of the volume and immensity of the forces of the air and deep. When the southerly gales come tearing across the Atlantic, up the mouth of the Channel, they rush into Mount's Bay, and, spinning round as in a caldron, beaten and resilient from headland to headland, make their last and fiercest onset on the serpentine walls of the Lizard Peninsula. From Poldhu and Mullion, over to the Lizard lights, is the climax of the struggle between the forces of earth and air, the rocks and tempests, in which the sea intervenes as the willing and mighty ally of the kingdom of the winds. It is a battle of armies in position, a set-piece of natural combat, in which the meeting of the hosts is veiled in mist and smoke and spoutings, and earth and sky re-echo the thunder of their war. The fighting-line is the foam-fringe, which

comes into action then, as we watch it from one of the black projecting towers of serpentine which guard some deep cove in the Lizard front. From the blue deep of the bay, under scuds of storm-wrack and shafts of light, the waves advance with a frontage of miles, blue rank behind blue rank, and ever rising and sharpening towards their summits. The front ranks pass by the watch-tower, bursting invisibly on the left where the buttress projects, but the right mile of wave has not yet hit the coast. Part does, smiting the heads of the cliffs in succession and exploding like mines in smoke and spray; part rushes on in the cove below till we see the back of the waves, green and translucent, as wrecked sailors do, rising between us and the shore, till the billow rises, curls over like a scroll, and then pours forward the rolling fields of foam. The whole frontage of the bay holds nothing but this sea-froth, into which the jade-green, sun-pierced mountains of water are ever pouring fresh floods from ocean's store. Acres and acres of foam lie weltering there, some dashing 100 feet over the squared, black, yellow-stained cliffs, some eddying round or falling back on the sands of the cove, some following the spin of the waters round and floating on half-seen solid sea, lapis-blue or green. This welter of the sea divides into three forms: the solid sea water; the white water, which is sea and air mixed by the toppling of the wave or its explosion on the rocks and precipices; and the true foam, which is made of sea-bubbles stuck together like a lump of skates' eggs, and often detaches into masses like sponges, large and small, and floats inland in such flights and incessant driftings as to form a separate and peculiar feature of the fringe of these Cornish precipices.

The spray, which dashes over the cliff-faces when unbroken waves hit the rocks, is solid water finely divided, wetting and stinging, and destroying or blighting even the hardy vegetation of this strange and awful coast. From the top of Gue Graze, near Kynance, and on the cliffs adjoining, the forms and force of foam may be seen as at a "private view," for no one is there to share the sight but the ravens and the falcon on the cliffs. Across the inlet is a wall of black serpentine, 300 feet high, veined with invisible green, and patched with orange below where the spray does not fall. The serpentine wall stands upright, above a black cavern, Ogo Pons ("ogo" means "cave" in old Cornish), bored out by the Atlantic waves. Above, the serpentine is capped with short turf and Cornish heather and thrift. The whole cove or bay is one inlet of green foam-edged, bellying surge, dipping, heaving, swelling, contracting and expanding, with the rolling froth eddying this way and that, and smashed and drowned at regular pulsations by the green and white outpouring waves from the main ocean. As these roll in like minute-guns their right flank hits the projecting cliff before they break, and as from a cannon's mouth the smoking spray rises in a column wide and high as a cathedral tower. From base to summit this column of spray ever drenches the cliff, and keeps it wet, black and bare. It curls over the summit, and throws itself, widened and wind-borne, on the turf mantle at the top, and as the spray of a fresh fountain makes all the grass green within the spread of its refreshing dew, so the pillar of salt spray has turned all the acres of grass on which it falls into a tawny brown and bronze. This spray is violently thrown; it does not float upwards; but the winds here help to carve the rock, even as the sand-grains carve the crags round the Sahara desert. Vexed by the spray, baked by the heat, and frozen in winter cold, the marble-like face of the serpentine cliffs cracks at first into square blocks, whose sheltered sides are slowly overgrown by an exquisite bloom of grays, and powdery yellows, and green lichenous dust, like pastel smoothed on a dark gray ground. These split and split again, and are then carried in tiny squares to the top of the cliffs by the wind. For the wind plays strange tricks as it strikes the cliff-face from the open sea. In a forty-mile gale blowing straight from the ocean you may stand on the cliff edge, if at a height of over 200 feet from the water, almost in a calm. This is one of the mysteries of this home of the wind and foam, and is explained thus: —

All the wind-force which strikes the cliff-face rushes upwards, perpendicularly with the face of the precipice, and with greater violence than the horizontal force which strikes the air above the summit. Thus the vertical ascending wind acts as a screen from the horizontal blast, and the watcher on the cliff is shielded from one blast behind the protection of the other. It is on this upward blast that the seagulls float in gales close to the cliff-face. It also scrapes off and carries upward from the serpentine little loosened cubes of the rock, green and dark azure, and streaked with bloody red where it is fresh broken, and lifting these above the cliff-top, drops them on the flat summit when the horizontal blast overpowers the ascending one. The turf is strewn with these little chips of the wind's undoing. Against lower cliff-faces the course of the wind is more wilful. The foam-flakes trace its currents and mark in their slow and devious flight the course and winding of these wandering winds. In Dollar Cove, a low-browed circular niche in the black coast, some thirty yards across, with a cave under the eastern side, the towering waves rolled before an ocean breeze on the ebb tide and piled masses of sea-froth, brewing like wort, 4 feet deep on the strip of sand which lay at the feet of the rock-face. Into the cove and against the shore, the wind blew steadily, and flakes and masses of the froth, of all sizes, from that of an apple to the rope fender of a coaster, detached themselves from the mass, rose, and followed the course of the wind. There were four main currents, each as clearly marked by the successive and slow travel of the froth masses in air as is the current of boiling water by the sawdust in a chemist's flask. Some rose on either side of the little horseshoe of rock, travelled slowly up the face of the cliff, and then moved off right and left inland along two depressions in the down above, where they made a long trail of slowly expiring bubble masses. Others, when they reached a point to the right or left of these ascending winds, turned backwards in a curve, followed the horseshoe towards the outer edges, and then curled back over the sea, following in the air almost exactly the same course as the refluent waters were taking below. This cove is possibly named from a Dutch brig, the "*Dollard*," laden with wheat, from Trieste for Falmouth, in 1862. One of the crew saved himself by jumping on to a rock and climbing the cliff. The captain, his son and four seamen perished, and the ship went to pieces in ten minutes. But a month later, at low water, some fishermen made their way into the cave, or "ogo," the bottom of which is always awash, and there found parts of the masts and spars of the "*Dollard*," which had been churned about in this subterranean cavern ever since the wreck. — *The Spectator.*

BOOKS AND PAPERS

MR. ALFRED WHITMAN'S new book[1] upon engravings deserves notice for two reasons — because such a book is eminently useful to collectors and would-be ones, and because being an official in the Department of Prints and Drawings in the British Museum, he speaks authoritatively and with knowledge — two qualities which do not always go together. The book explains the various kinds of engravings — mezzotints, etchings, line, stipple, printing in color, aquatint, woodcuts and lithographs. The illustrations are some eighty in number, mostly by the half-tone process, but, in order to show the different styles of technique of the originals, some of them are reproduced in collotype — a distinct advantage. Etchings reproduce line for line, but line-engravings and mezzotints lose their especial technique by the half-tone process, the screen used destroying the texture of the original work, or, rather, it adds another texture to it.

Mr. Whitman gives a chapter upon each branch of engraving, and, incidentally, upon the various frauds indulged in by dishonest dealers of former times and of the present day, and so instructs collectors as to the rocks to be avoided. He also gives a chapter upon prices attained in these latter days. Fashion and fads, of course, rule the collection of prints as of other things worth collecting, but the prices which colored prints (printed in colors) have fetched in London lately seem exorbitant, and Mr. Whitman points out that an amateur may make a very good collection of engravings at small cost, if he be content with good specimens, but of less popular subjects. Thus, although a Rembrandt etching (the "Rembrandt with the Sabre") fetched £2,000 at the Holford Sale, an amateur known to the author picked up some genuine and very good ones at old shops for 6*d.* apiece! These are the prizes which are sometimes obtained by those who poke into dirty portfolios in squalid shops. Fine French line-engravings may be bought reasonably now — they are not in fashion; whereas, if you want mezzotints after Reynolds, you must bring a heavy purse. In the one case two figures may be enough; in the other, the price may rise even to four figures.

Morland's colored prints fetch large sums: they are the fashion; but it is a fashion which will probably decline. His pictures of animals are, of course, worth the prices they fetch, but the transcriptions printed in colors of his figure-subjects are very inferior.

As in books, so in prints, the least thing will enhance or diminish value. A first edition of "*Martin Chuzzlewit*" with the hundred pounds on the title-page printed thus, "100£," is of much value; but the later first editions where the correction appears as "£100" is of next to none. So the "Portrait of Ephraim Bonus" etched by Rembrandt with a black ring, sold in 1893 for £1,950; whereas at the same sale (Holford), an impression in the second state, with a white ring, went for only £135. This makes the difference; as it is known that only three impressions of the former are known, all the others are of the second state. As of these three impressions in the first state one is permanently preserved at Amsterdam, while the second is in the British Museum, the Holford impression, as in the case of the "Rembrandt with the Sabre" was the only one that could possibly ever come into the market.

A reproduction of "La Rue Transnonian," lithographed by Honoré Daumier, shows that artist in all his dramatic force.

Mr. Whitman has hit upon a very useful idea in reproducing a portion of some of the prints enlarged three times. It is always difficult to describe art techniques, but by these examples we see at once, say, the effect of the "rocking" process upon a mezzotint ground; if we could have had a photograph of the "rocker" we should have had still less difficulty in understanding this particular process.

The description of the vicissitudes of an equestrian portrait of Charles I. by Vandyke are strange. It is in line and has passed through five stages. No. 1 is without a head. No. 2 has an etched head of a wigged and moustachless gentleman, which might be Marlborough or William III. No. 3 is Cromwell. In No. 4 Charles re-appears, and in No. 5 we see old Oliver resuscitated! The erasures round the heads are quite plain, and speak of the popularity

[1] "*The Print-Collector's Hand-book.*" By Alfred Whitman. London: Bell & Son. 1901. 15*s.*

and unpopularity of the two persons. As the pendulum moved toward monarchy or democracy, so this copper-plate was placed under the hands of the engraver to bring the head up to date (!) in representing alternately the King and the Lord Protector.

NOTES & CLIPPINGS

THE PROPER POLICY FOR PICTURE-GALLERIES. — Mr. Claude Phillips is up in arms over the latest manifestations of that curious method which is followed by the authorities of the National Gallery in adding to its possessions. A huge altar-piece by Signorelli has been bought for Trafalgar Square from the Mancini Collection at Citta di Castello. Although it is authentic, the critic argues that it is far from being a worthy example, and that as Signorelli is already adequately represented in the National Gallery, this immense painting is undesirable whether the price paid for it was a high or a low one. He pertinently advances the idea that it is better for the authorities to hoard their money and wait for first-rate opportunities than to buy superfluous works like this, especially as the outlook in the picture-market is well calculated to make possible purchasers put themselves in readiness to spend freely. "The wave of disintegration is again passing over England," says Mr. Phillips, "and the many who look upon the possession of great and epoch-making works of art as one of the national glories must tremble when they remember the breaking up in comparatively recent times of the famous Blenheim, Dudley, Ashburnham and Francis Hope collections, and the partial dispersal of one of the most interesting of all — that of the Earl of Northbrook. Transatlantic capital batters in now, by sheer force of metal, such few doors as are not thrown wide open to meet it half way. Among the collections which have already suffered from its seemingly irresistible encroachments — and may, therefore, suffer more in the future — are those of Castle Howard, Cobham, Warwick Castle, Kingston Lacy, and, alas! even that of Dorchester House, which, as one of the finest and best-chosen private galleries in the Kingdom, every one must honestly desire to see maintained intact, or, if it should come to the worst, handed over intact to the nation." The National Gallery has long suffered from the short-sighted policy to which Mr. Phillips refers. Either through the bad judgment of the Director, through the disagreements of Trustees, or through the lack of funds which should easily have been procured from private sources when Government grants were unavailable, good pictures have been allowed to pass into the hands of foreign buyers, and the sense of loss has been aggravated among outside observers by expenditures as ill advised as the one to which specific exception has just been taken. There were groans in London last summer when the chance to buy a fine Hals was missed. The Continental museums are better off. The directors in Amsterdam, Berlin, Paris, Vienna, and Munich are kept so well informed that they or their representatives are promptly on the scene whenever there is a chance of acquiring a valuable work of art; and, somehow, they seem able to raise funds enough to make them formidable competitors when the sale comes off. There is a lesson here for us. The Metropolitan Museum is receiving every year more and more generous support, and, indeed, the recent Rogers bequest is one to excite envy among the directors of art-museums all the world over. But it is important that the Metropolitan should be kept constantly supplied with a really large sum in cash for the purchase of such works as may come into the market, and that it should be represented abroad by agents on whom the Director and Trustees might rely for early and absolutely trustworthy information and for that discretion in the making of purchases which is as necessary as the money itself. — *N. Y. Tribune.*

PARMA, THE CITY OF THE FARNESI. — On almost every Italian town, whatever succession of masters it may have known, some one family has left its dominant mark, and Parma is distinctively the city of the Farnesi. Late-comers though they were, their lilies are everywhere, over gateways, on palace-fronts, and in the aisles of churches; and they have bequeathed to the town a number of its most characteristic buildings from the immense unfinished Palazzo della Pilotta to the baroque fountain of parti colored marbles which enlivens, with its graceful nymphs and river-gods, the grassy solitude of the palace square. To Rannuccio I, the greatest of these ducal builders, Parma owes the gigantic project of the Pilotta, as well as the Farnese Theatre and the University. To this group Duke Ottavio, at a later date, added the charming "Little Palace of the Garden." . . . The Farnese Theatre is one of those brilliant improvisations in wood and plaster to which Italian artists were trained by centuries of hurriedly organized *trionfi*, state processions, religious festivals, returns from war, all demanding the collaboration of sculptor, architect, and painter in rapid evocation of triumphal arches, architectural perspectives, statuary, chariots, flights of angels, and galleons tossing on simulated seas: evanescent visions of some *pays bleu* of Boiardo or of Ariosto, destined to crumble the next day like the palace of an evil enchanter. To those who admire the peculiarly Italian gift of spontaneous plastic invention, the art of the *plasticatore*, to borrow an untranslatable term, such buildings are of peculiar interest, since, owing to the nature of their construction, so few have survived; and of these probably none is as well preserved as Aleotti's Theatre. It is true that the painted ceiling is gone, and that the splendid Farnese dukes bestriding their chargers in lofty niches on each side of the proscenium are beginning to show their wooden anatomy through the wounds in their plaster sides; but the fine composition of the auditorium, and the Olympus of plaster divinities peopling the niches and balustrades and poised above the arch of the proscenium, still serve to recall the original splendor of the scene. The dusty gloom of the place suggests some impending transformation, and when fancy has restored to the roof the great glass chandeliers now hanging in the neighboring museum, their light seems to fall once more on boxes draped with crimson velvet and filled with lords and ladies in the sumptuous Spanish habit, while on the stage, before a perspective of fantastic colonnades and terraces, Isabel and Harlequin and the Capitan Spavento, *plasticatori* of another sort, build on the scaffolding of some familiar intrigue the airy superstructure of their wit. — *Edith Wharton in Scribner's Magazine.*

SAFEGUARDING THE CITIZENS' HEALTH. — A recent decision of the Appellate Division (Third Department) of the New York Supreme Court in the case of Margaret Munn *vs.* the City of Hudson (61 App. Div., 3423) holds that where a city allows its sewerage system to get out of repair, the householder whose property is injured can recover damages not only for the injury done to the property, but also to the health of the householder. In some respects this seems an advance on the idea hitherto entertained in New York. In this case the city built its sewer in such a negligent and insufficient manner that after several years' use part of the sewer became filled up, with the result that injury was done to the property and to the health of the householder. The trial resulted in a verdict of $800 for damage done the property and $1,000 for injury to the health of the plaintiff. In sustaining this verdict, the Appellate Court said the facts were such as to have given the city ample notice to repair the sewer. The city argued, however, that, as a matter of law, damages could not be recovered for injuries to health. Replying to this argument the Appellate Court said: "It was the duty of the defendant to use reasonable care in constructing the sewer according to the plans and specifications, and it was also the duty of the defendant to use reasonable care in keeping the sewer in proper repair." Accordingly it followed, the Court held, that "where, by reason of the negligence of a municipality, a trespass is committed upon premises by allowing the contents of a sewer to overflow thereon and a private nuisance is thus created, we see no reason why the owner of the premises cannot recover as damages, not only the injury to the property, but all other damages that are the natural and proximate result of the wrong. The damages must depend upon the proof in each case, and are only limited by the ordinary rules that require that they should not be remote or speculative." This decision, if sustained, may lead to much interesting litigation as to how far cities may be bound to see that householders do not suffer in their health from the negligent failure of cities to keep their sanitary arrangements in order. — *N. Y. Evening Post.*

NOTES AND CLIPPINGS. 32

TOO late in the season to allow us to perfect our plans and make announcement earlier, we determined to make a change in the manner and method of publishing our International edition, and we now give notice that the change impends and will have effect in the second quarter of the year. The change consists simply in gathering the extra illustrations which constitute the International edition into four quarterly issues in place of their being, as now, scattered through thirteen weekly issues. The result will be that the subscriber to the International edition will receive each week a copy of the Regular edition and with each quarter a quarterly volume in which will be collected the gelatine and other International plates. That is, a subscriber will receive exactly what he now receives, but it will reach him in what, we believe, will be a more acceptable and agreeable form. Amongst other advantages incident to this condensation of matter is the fact that it will enable us to publish in the same issue all the plates in illustration of a given building, instead of being forced to let them dribble out, a few at a time, in four or five different weekly issues, as in the past. — *From our issue for Jan. 4.*

THE Commission for beautifying the city of Washington, among the other suggestions which it makes, provides in its plan a suitable place for a large hall, which can be used for exhibitions of various kinds, as well as for the inaugural ball, which occurs every four years, and for other State festivities. The need of something of the kind has really become pressing. State balls or receptions are not infrequent in Washington, and would be more common if there were a place to hold them in, but, unless, as sometimes happens, a temporary shed is built for them, or a tent set up, it is necessary to find room for them in the Pension Office, or some other structure which, to say the least, was never intended for such a purpose, while the preparations for the entertainment interfere very seriously with the work of the branch of the public service whose hospitality is called upon. Some twenty years ago, a ball was to be given in honor of an important assemblage of military men with their families in Washington, and, as nothing better offered, a huge tent was set up for it. The night before the ball the tent was blown down by a furious snowstorm, and the Government, with the never-failing courtesy which is characteristic of Washington, lent the Capitol to the distracted managers of the entertainment. It cannot be said that the sandstone pavement of the Rotunda was particularly favorable to dancing; and, although very few balls have been held in a more dignified room, it would be possible, without great expense, to build a structure large enough to hold the company of an inauguration ball, and, at the same time, beautiful and comfortable, which would be useful in many ways, as for example, for exhibitions of flowers and pictures, patriotic fairs, receptions to distinguished people, and so on. Senator McMillan has already introduced a bill for the erection by the Government of such a structure, and, although there is little probability that Congress will pass the bill, the matter has excited so much interest that a meeting is to be held in Washington on the fifteenth of February to see whether a private corporation cannot be formed to build and maintain a structure of the kind, asking the Government only for the concession of a site on public ground. In view of the many public or semi-public uses to which the building would be put, it is probable that Congress will readily grant this, and it is much to be hoped that the undertaking may be carried out.

A CASE of importance to architects came up recently in the Supreme Court of Indiana. An architect contracted with a public Board of Commissioners to furnish plans and specifications for a certain building, and superintend its erection, for a certain percentage on the cost of the completed building. It was stipulated in his contract that the building should not cost more than a certain sum, and that he should make necessary changes in the plans and specifications without additional expense; and the contract also provided, presumably by implication only, that the architect should pay all loss or damage due to his own mistakes in preparing plans, specifications or contracts, or in superintending the erection of the building. After the original plans and specifications were made, the Commissioners directed changes to be made, which greatly increased the cost of the building, and the architect superintended its execution at the increased cost. The question before the Court, which was decided unfavorably to the architect by the court below, was whether, under his contract, the architect was entitled to a percentage on the extra cost of the building over the sum originally stipulated. The Supreme Court reversed the decision of the lower court, and held that the architect was, under the circumstances, entitled to his percentage on the entire cost of the building as finally completed. The attorneys for the Commissioners thought that it strengthened their case to claim that the contract with the architect was illegal, under a statute forbidding "commission or percentage contracts with State or county officers"; but the Supreme Court held that the case in question was not within that statute.

THE New York builders, with good reason, are endeavoring to prevent the adoption by the Assembly of a bill to tax mortgages, on the ground that, as they are obliged to carry on their business with money mostly borrowed on mortgage, the tax would add greatly to their burdens. The people who vote for laws taxing mortgages often have a vague idea that they are in this way getting money out of the "money-lenders," or the "Shylocks," or whatever else they choose to call them; but, in practice, all mortgages on real-estate contain a clause by which the borrower agrees to pay all the taxes which may be imposed, either on the estate or on the mortgage, and, as no legislation can, under the Constitution, set aside an agreement of this kind, the taxation of the mortgage, independent of its abstract justice, simply increases the burden of the borrower. In the case of builders, who often carry a burden of from fifty to a hundred thousand dollars of mortgage-loans on a capital of a thousand dollars, a tax on the mortgages, which they would have to pay, would soon ruin them. Supposing the mortgages to bear the usual rate of taxation of personal property, which would be, in New York, about two per cent, the additional burden which would be imposed on them every year would be, in many cases, more than their entire capital, and more than the income which they could reasonably hope to derive from their business for the support of their families. In practice, the matter would be worse than this, for, as most builders would be absolutely unable to pay such a tax on their usual amount of borrowed capital, they would soon be overwhelmed with foreclosures, and ruined; while such as held out or passed through bankruptcy would find their operations limited to very meagre proportions by the smallness of the loans on which they could pay interest.

A CURIOUS and important case has just been decided by the New York Court of Appeals. Some twelve years ago, a block of three apartment-houses was built on three contiguous twenty-five-foot lots in New York by the owner of the three lots, who made the walls between his houses party-walls. Not long ago, one Schaefer contracted to buy one of the lots with the house standing on it. After he had agreed to buy, he learned that the party-wall, for a distance of twenty-seven feet, was entirely on the adjoining lot. He sued the person from whom he had agreed to buy for damages, on the ground that he had not a complete house on the lot in question, since the support of a portion of the beams was on neighboring property. This view was confirmed by the Supreme Court, but the Court of Appeals held a different opinion, saying that the original owner of the three lots, by resting the beams of one of the houses on what was supposed to be a party-wall, but which was really on the adjoining lot, created thereby a servitude on the latter lot, so that Schafer was entitled to rest his beams on the wall in question, as long as it should stand; and, as his house was so much wider in consequence, he was benefited, rather than injured, by the mistake.

THE establishment of a Germanic Museum at Harvard College comes at a very appropriate time. Large as the German population of the United States is, Americans in general know almost nothing of German literature and much less of German art. Even German industry is just beginning to make its way here, and, while many of our merchants and manufacturers have now their regular connections in Berlin, or Elberfeld, or Hamburg, they do not say much about them, and the average citizen, who is occasionally surprised to see a German mark on the stockings, or scissors, or pen-knives that he buys for his family, as being of the best quality obtainable, would be still more surprised to hear that German manufactures are to be found everywhere; that a large proportion of the richest mines, the most important railroads, and the finest steamships in the world belong to Germans, and that the larger manufacturing cities of Germany have, within the past twenty years, surpassed in rapidity of growth anything known, even in this country, outside of a mining camp. This rapid development of Germany has unquestionably been of great benefit to civilization. Independent of the traditions of sober probity which still rule in German business affairs, the intelligence of the Germans in making practical use of the scientific reasoning in which they excel all others has been of incalculable advantage to the world, and there is hardly a household in Europe or America which does not enjoy some comfort which, except for the Germans, would have been beyond its reach.

IT is probable that the industrial capacity of the Germans will through the force of circumstances soon become more familiar to us, but there is a whole world of German sentiment and feeling which, if it were better known, would appeal particularly to Americans. Unfortunately, perhaps, true sentiment does not put itself forward like the commercial spirit, and the friends of German art, by the forms of which German feeling is expressed, must make some effort to bring it to the attention of their kinsmen on this side of the ocean. For such an effort the new Germanic Museum offers an opportunity which will, we hope, not be neglected. It is reported that the Emperor of Germany, who is a sincere admirer of the American character, and earnestly desires a better understanding between the two nations, has interested himself in making a collection of casts and other examples of German art to be presented to the Museum. This would be a very pretty compliment, not only to the Museum and the University, but to the American people; but even if the report should prove to be without foundation, it would still be possible to get together, in the building which the University has set apart for the use of the Museum, a very interesting assortment of objects, illustrating, not only German art and history in general, but their variations, Prussian, Rhenish, Saxon and Bavarian, from Charlemagne down to our own time.

THE poor consumers, who meekly look on while Trust magnates are fighting among themselves, and wonder whether the fray will end in any relaxation of the iron grip of the magnates on prices, will find interest just now in the movements in the glass manufacture. It will be remembered that, not long ago, the American Window Glass Company executed a masterly stroke of policy in making an agreement with the glass-blowers' union, by which the members of the latter, in consideration, it is said, of a large number of shares of the Glass Company's stock, together with other valuable considerations, agreed to work only for the Trust, the latter agreeing on its side to employ only members of the union. As the union comprises only about two-thirds enough men to operate the window-glass factories in the United States, and, practically, refuses to admit any new members, the combination between the monopoly of employers and the monopoly of labor was looked upon for a time as invincible. It appears, however, that a cloud has come over this delightful scene. A window-glass manufactory is not a very costly affair, and from time to time, small parties of glass-blowers, dissatisfied with union methods, have raised a little capital, and entered upon manufacturing for themselves. These small concerns have not until lately been important enough to interfere with the monopoly of the Trust, and, taking advantage of the high prices established by the latter, they have prospered. Now, the aggregate production of all the factories, including those of the Trust and the independent concerns, is greater than the consumption, and it has become a serious question which party shall curtail its operations. Immediately after the alliance between the American Company and the union, the independent concerns found it so difficult to get men that it was reported that all of them were closed, but this state of affairs lasted only a short time, and matters are now as bad as ever. Each party is suspected of designing to make a sudden and great reduction in prices, in order to secure heavy contracts for the next season; but each party evidently fears difficulty in getting men to carry out such contracts as it may secure. The union, apparently foreseeing defections from its ranks in case of the inability of the Trust, which protects it, to control the business, has voted to admit "apprentices," to the amount of ten per cent of its total membership. The object of this proceeding seems to be to make sure of supplying the Trust with the men that it may need, at the same time that the regular union manœuvres are carried on to prevent the outside concerns from getting men. Whether it will succeed remains to be seen; but, meanwhile, it may be observed that no Trust, or combination, or monopoly can long keep up prices of goods which are being manufactured at a rate fifty per cent greater than the consumption. If production can be checked until it equals the demand, prices can be maintained; but, in order to check production, some one must go out of business, and nobody is likely to do that so long as profits are large. The earlier Trusts kept down production by paying the proprietors of competing manufactories to let their establishments lie idle, but this is out of the question in the window-glass manufacture, and the chances seem to be that the contest will, for a time, at least, take the form of a radical cutting of prices.

THE importers of antiquities are having a hard time just now, under the new Custom-house regulation, by which the price actually paid for articles imported from abroad is not regarded in the collection of duties if the examiners in this country think that they were bought too cheap. Boston is, probably, the best market in the world for the sale of miscellaneous bric-à-brac, and two dealers have recently had their importations confiscated for undervaluation, the appraiser, in one case, valuing at two thousand dollars each certain tapestries, smaller, and probably, not very much better, than pieces which have sold for twenty-five dollars or less. Under the Custom-house regulations, if the examiner in this country thinks that imported articles are worth over fifty per cent more than the declared invoice cost, they are absolutely confiscated, and the owner can only obtain them by buying them of the Custom-house at the appraiser's price, in addition to what he may have paid for them originally, or by waiting until the confiscated goods are sold at auction for Government account, and bidding on them. It is hardly necessary to say that, if our Custom-house inspectors were not men of perfect integrity, it would be easy for them to appropriate anything in a tourist's or importer's trunks to which they might take a fancy, by the simple process of rating the value fifty per cent higher than the cost, seizing it, sending it to the Government warehouse, and, at the auction sale, quietly having it bid in by a confederate. In the case of the tapestries, for example, it is incredible that two thousand dollars each should ever be bid for articles of the kind, in connection with the old boots, damaged hides, broken crockery and other staples of Custom-house auctions, and an understanding among the officials might easily throw all the bargains into their hands.

THE RECENT EXCAVATIONS NEAR POMPEII.

NEAR Pompeii, just now, they are exhuming invaluable relics which belong, probably, to some faubourg of that lovable, but unfortunate, town. These excavations are being made about a kilometre from the walls and at 200 metres from the mouth of the Sarno. After removing a layer of half-sedimentary and half-volcanic deposit, they have come upon an old portico, with the remains of travellers and visitors who had sought refuge there.

In accordance with some of the indications, and, perhaps, after a last effort of imagination, some have asserted that it must be granted that there were recognized amongst the bodies discovered the *familia* of Pliny the Elder, Pliny himself being present in the guise of one of the bodies most richly clothed and evidently that of the most important personage. But this is, doubtless, only a very audacious hypothesis put forth by a fertile poetic imagination impressed by certain historic reminiscences. It is far more prudent to feel that we are in the presence of the relics of a band of fugitive Pompeians whom the cataclysm overwhelmed at the place where the excavation brings them to light.

It is almost beyond doubt that the body of the great naturalist of antiquity was neither abandoned nor forgotten in the disaster. They found it the next day, when the incandescent showers had ceased, when the black clouds of mephitic vapor no longer rolled over the shores of Campania, and, in the celebrated letter which Pliny the Younger addresses to Tacitus, he says that they found "*corpus integrum, inlæsum, opertum ut fuerat indutus*," and expresses himself in terms which prove that his uncle was not buried in a shroud of lava, as were so great a number of his compatriots. He supposed, even, that he died of asphyxiation, since his body showed no sign of agony, but was calm and serene, without any contractions of suffering or tragic agony, and was still, according to his nephew, "*habitus corporis quiescenti quam defuncto similior*."

However this may be, it will not be easy to determine the condition and the names of the unfortunates overwhelmed between the Sarno, a little stream of Campania, and the sea, burned by the incandescent mud of Vesuvius, blinded by ashes and exhausted by heat, at the very moment when they were about to secure their safety through embarking on a galley which would have transported them into the open sea. But one can reconstruct the scene of their agony: without difficulty, one calls up the torments and the horror of their last hour, between the land transformed into a lake of hot mud and lava, the air changed into a burning furnace, and the sea lashed into a whirlpool which refused to receive them.

There are seventy of these bodies lying under the massive arcades of the portico, upon the line of the road from Pompeii to Stabia; they are the relics of all classes of unfortunates — men and women, old and young, rich and poor, laborers with calloused hands, and rich epicureans. Some are covered with gold; there is one of them, amongst others, which is distinguished by its rich jewels and amulets, and which must be that of the most important personage, the chief one of the group. Near by his pelvis, which time has deprived of its covering, a girdle was found, and a sword with coquille hilt, which leads one to think that its wearer was a seaman. It remains for the learned amongst us to say whether we are in the presence of the ashes of the edile of some maritime village, of the captain of a galley, or of an admiral. This last hypothesis is that which is preferred by those fertile spirits who rush too speedily to a conclusion, and who have asserted that this is the corpse of Pliny the Elder.

But Pliny, let us repeat, has not lain eighteen centuries under the ruins of Pompeii; when he was found — and this supposition is as easy as it is natural — his relatives and his fellow-citizens, aghast, could not be deprived of the pleasure of erecting to him a mausoleum worthy of his deserts. So, if one must expect everything else from the lavas of Pompeii, so fertile in historic and artistic treasures, one must search elsewhere for the ashes of the grand Roman naturalist.

The wealthy personage whom I have just mentioned, whether edile or admiral, the one whom some suspect to be Pliny, and of whom, perhaps, some day we shall know the real history and the name, does not seem to have belonged to the Pompeian colony. Everything leads to the belief that he was some functionary travelling about his duty or about his pleasure. I need no better proof of this than the composition of the little court which accompanied him and the nature of the baggage which followed him. What likelihood is there that an inhabitant of Pompeii, on the approach of that unheard-of catastrophe, when the flames were darting from Vesuvius like a condemnation for the town built about its feet, would have taken the time to gather together his terror-stricken slaves, and brought together the baggage necessary for a journey? Terror causes one to forget the rules of social life, the little precautions, and effaces all hierarchic differences. This is so simple and true that it seems almost puerile to state it.

Now, here the unknown who interests us met his death surrounded by his court, by his entire *familia*. A few paces from him fell his domestics, at the proper distance required by respect; the death which overwhelmed him laid low at the same time the slave who bore his toilet-service — a precious collection of silverware, finely engraved; the slave physician, near whose skeleton lies his medicine-case, filled with surgical instruments of very careful workmanship, and all the other servants; the one who walked at the head of the procession, lighting the way with his lantern, in the plain obscured by the burning cinders of Vesuvius, a veritable Colossus who measured six feet in height, fell without letting his lantern from his grasp; and farther on were men of herculean proportions, the litter-bearers who must have abandoned their master on his reaching the portico; they have discovered the remains of this litter, without any human relics near it, without an indication which allows one to imagine that its master perished in it; the wood of the vehicle was destroyed, of course, but all the metal ornaments, skilfully wrought, remain intact — amongst others, a fine head of Victory surmounted by an eagle which must have crowned the canopy.

The long portico of the Sarno, supported by robust columns of masonry and brick pilasters, covered with white stucco with red bases, is one of those constructions, so numerous along the course of the old Roman highways, where the voyagers rested during the heat of the day, and where their horses found vast drinking-troughs. Behind the portico rises a mass of structures, a series of sixteen *tabernæ*, or shops, the seventh of which is distinguished by its panels separated by violet-colored pilasters and ornamented with yellow framework around paintings representing bacchic scenes; upon the walls at the back is painted, under the figure of the household god, the goddess of the River Sarno. This shop, then, was a wine-shop; the marble table which is found near the door takes the place of our bar-counter, over which are served drinks. By the door of this wine-shop were found twenty human skeletons, amongst which was one of an infant, and some objects which these fugitives were carrying away: a golden collar, an aureus of Domitian's date, ear-rings, bracelets in the form of a serpent, with eyes of emerald, golden rings, vases, silverware, silver and bronze coins, and so on. In another group were more jewellery and other objects of art: small mounted emeralds, a bracelet finished with a lion's head, a small bust of Silenus, another, in bronze, of Minerva, and a statue of Mercury. It would take too long to enumerate all the little marvels of jewellery which are still being brought up from these excavations on the Sarno. I will content myself with mentioning certain objects, such as a box, divided into several compartments, still containing the remains of color, a pair of scales, more than a hundred fish-hooks and lead sinkers for the fishermen's seines, amphoras of terra-cotta, some of which were painted and enriched with inscriptions, one of them bearing about the neck an inscription which boasts the quality of the wine contained within, the facts concerning its origin, and the name of the vine-grower who produced it on the slopes of Vesuvius and who was sending it to his friends in the city; another amphora still contains the remains of pickled fish, which indicates that the wine-shop was not only used as a drinking-place, but that there were also sold there the coarser foods, at low cost, for the workmen and small tradespeople of the neighborhood.

The money found also has its importance. Although a great many of the pieces have been eaten and deformed by chemical and atmospheric action, and have become in consequence unrecognizable, it has been possible to classify a large number, which fact does not lack a distinct value. In the first place, there are forty-five gold pieces of the times of the following emperors: Augustus, Tiberius, Caligula, Claudius, Nero, Vespasian, Titus and Domitian. Seven hundred and ninety-five are in silver and belong to the times of the Republic and these same emperors, while there are thirteen hundred and twenty-two bronze pieces, all except one dating from imperial times.

From all these indications and from other numberless little details, which would be tedious to enumerate, but especially from the presence in this place of certain articles, — the fish-hooks, for instance, and the instruments used in the making of nets, leaden weights for nets, the anchors and bronze naval ornaments, — it has been inferred that the ruins which are now being brought to light are those of a maritime suburb of Pompeii. Their position gives yet more weight to this hypothesis, for, as we have said, these ruins are at about a thousand metres' distance to the south from Pompeii, and two hundred from the mouth of the Sarno, which formed a little natural harbor. Nothing is more likely than that at this spot on the road from Stabia should have been built the portico in question and the poor habitations of the fishermen and sailors built up against it. So there should have been found here only a few bodies, a few simple amphoras of terra-cotta, a few jewels, if the population of this maritime suburb of Pompeii had alone found their death at this place. But from the city, from the villas of the neighborhood, some fresh from an orgie, with their heads still crowned with roses, others leaving their work or breaking short off in their journey, numberless groups hurried towards this little port in the hope of embarking there and entrusting their lives to the waves; but the absence of boats, and especially the condition of the sea, denied them this last chance of safety, and all found the same frightful death under the arcades of the portico.

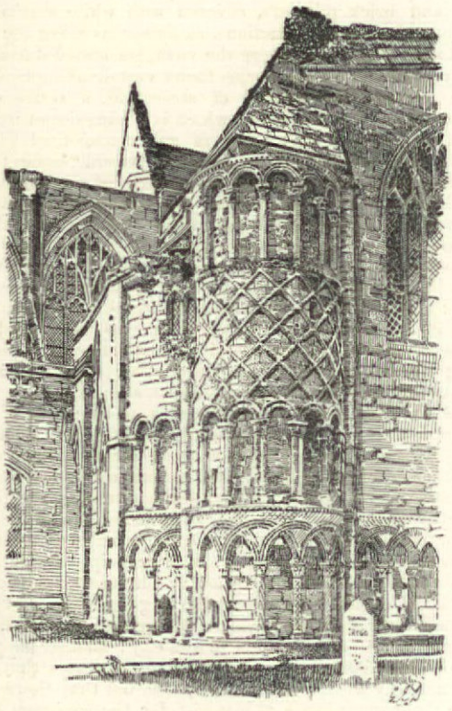
No corpse of Pliny, then, is here, but merely that of some patrician, some dignitary who was passing along the road from Stabia, and had reached the spot where this road crossed this fishing-village, a fact which does not prevent these excavations on the Sarno from being of very great importance, for they will serve to define more closely the physiognomy of the city celebrated for its unique misfortune and clear up certain obscure points in the customs of Pompeian life in the year 79, which we have known only imperfectly up to the present time. So these investigations are being prosecuted with much activity, in spite of the difficulties which are due to the infiltration of water from the Sarno.

H. MEREU.

DOMESTIC ARCHITECTURE IN ENGLAND DURING THE MIDDLE AGES.[1]—IV.

THIRTEENTH CENTURY.

THIS period of architecture is known as the Early English, or "First Pointed," and in English history extends through the reigns of Richard I, John, Henry III and Edward I (1189–1272). These were troublous times in England: the Crusades to the Holy



Christ Church, Hants.

Land under Richard Cœur de Lion; John disputing the authority of the Pope in matters ecclesiastical, ending, however, by his becoming the Pope's vassal and paying tribute; internecine warfare between the King and the Barons, and the wresting by the latter of "Magna Charta," held sacred to this day as the foundation of English liberties.

In Henry's time the first great council of the realm was summoned by Simon de Montfort, an assembly of the "King's tenants," attended also by the Barons and clergy (those, at any rate, who were favorable to the Earl), and this became the first step in the formation of a parliament.

Settlements of students under independent masters not attached to any ecclesiastical foundation were formed at Oxford during the twelfth century, and colleges within the universities were incorporated and endowed, showing the progress in learning during the time under consideration.

These, too, were the times of Robin Hood and Friar Tuck, as told by Sir Walter Scott in "*Ivanhoe*"; of Fair Rosamond and of Thomas à Becket.

The latter part of Edward's reign (1272–1307) is more properly classed with the next, or Edwardian, period.

Towards the close of the twelfth century a remarkable change set in: the arch, that had throughout all past ages and centuries been semicircular, became pointed, an acute junction of two segments of a semicircle; a change so fundamental, so conspicuous, that it entirely diverted the normal method of building and opened up hitherto undreamed of possibilities.

How the pointed arch arose and became an essential element in the architecture of the period is lost in the mists of ages; the interlacing of two circular arches in superficial decorative arcades was not uncommon, as, for instance, Christ Church, Hants, and Castle Acre Priory, which are late Norman; the Crusaders, too, would in all probability have met with the same features in their wanderings in Sicily and France. Flying-buttresses, which spanned the aisles of the Norman churches, were segments of circles butting against the vertical walls of the nave, and demonstrated the stability of one segment.

If we can conceive the necessity arising from hurriedly adapting the centres over which a series of wide semicircular arches had been turned (as in the case of reducing an opening in rebuilding), it is clear that any such reduction would be made by cutting out the centre portion, and bringing together the two segments to fit the opening. We should thus have a pointed arch formed by two similar segments butting at the apex, and, curiously, as lending evidence in support of this contention, we actually find in numerous cases two such segments butted together at the apex, and not built with a key-stone, as before. Pugin, the great apostle of Gothic architecture, was so impressed with this not uncommon construction that he maintained that it was the true Gothic principle: that the Gothic, or pointed, arch was a keyless arch.

When we note that every salient feature was clearly traceable to a defined necessity, and that it was the simplest solution of the case, it is not unreasonable to suppose that the first pointed arch was the outcome of some defined necessity, and that when first seen it was so transparently perfect and beautiful, and opened up such vast possibilities, that it spread abroad, and was adopted by the monastic architects throughout the length and breadth of Southern and Western Europe.

It is possible that among extant examples of the pointed arch the earliest may be found in the Isle-de-France, at Paris, but, with the great intercourse among nations due to the Crusades, each country, no doubt, subscribed its quota of advance. These were progressive times!

The facility of the pointed arch was, however, seized on with avidity; the soundness of its construction, when once seen and appreciated, led the builders of Western Europe to dare to span spaces not before attempted, and to raise their vaults to greater and still greater heights, as we see at Westminster Abbey, 120 feet, and later on, at Beauvais, 147 feet to the underside of the groining. It led up to forms of lofty grandeur soaring skywards, culminating in the spire of Salisbury Cathedral carrying the cross 400 feet above the great plain from which it so grandly rises.

We may broadly note, therefore, that, prior to the last quarter of the twelfth century, all arches without exception were semicircular, and that during the last decade most of the arches were pointed, and that after the commencement of the thirteenth century till near the close of the sixteenth century semicircular arches are never found in work executed during that period.

The juxtaposition and mingling of styles so frequently noticed is due to rebuilding, enlargements, or alterations at subsequent dates which the architecture and detail clearly define. The fundamental principle is that, during any one period, the people, by common consent, spoke, dressed, and built alike. The fashion was all-pervading, and the style in building is the ear-mark of the period. The buildings remaining to us are the history and the romance of by-gone days written in stone, and, when correctly understood, are a study of surpassing interest. They are essentially anecdotal, and remain scattered over the country as feathers dropped from the wings of Time.

The monastic buildings were always in the van of progress, and in them every feature is found more conspicuously developed. We notice, as compared with the work of the twelfth and thirteenth centuries, that the general proportions are more slender and more lofty: the arches are pointed instead of semi-circular, and with a different type of moulding; the chevron decoration has disappeared, and deeply channelled mouldings have taken its place. The piers are composed of clustered shafts as compared with the huge circular shaft of the preceding styles, the external shafts are often detached, and sometimes executed in local marbles, horizontal bands or zones appear on the shafts, the bases have deep hollows between bold, rounded mouldings. The capitals also are totally different, the former cushion type with the square abacus and the angles of the bell rounded off to the circular shaft has been replaced by a well-developed moulded abacus, and the bells of the caps are decorated with freely undercut conventional foliage, springing from the neck and clustering under the abacus, showing a total departure from precedent.

A good deal of rude sculpture is found decorating large doorways, conventional in character, often grotesque, but vigorous, and well adapted to its purpose as decorative enrichment.

The windows are not only pointed, as single lancets, but increase in width and become divided into two or more lights by mullions, which gradually decrease in thickness, the centre light in triplets being the highest. These three lights gradually become enclosed within one external arch, the centre one being the highest, or the head is filled-in with a single stone pierced with foliated openings. This is called "plate tracery," which towards the close of the century gave way to "bar-tracery," which in section is similar to the mullion, but constructed with small stones with joints radiating from the various centres, usually dowelled together, evidencing a great advance in scientific masonry.

The doorways are deeply recessed, enriched in the jambs with slender detached shafts of local marbles and decorated with carving; the arched mouldings are deeply undercut, decorated with the peculiar dog-tooth ornament and the conventional foliage characteristic of the period, entirely replacing the "chevron" and "boutel" ornamentation of the past period.

Surface decoration with the diaper replaces the scale decoration of the Normans.

Pointed vaulting with diagonal ribs replaces the barrel vault of the thirteenth century.

Roofs become high pitched, replacing the flat roofs of the Normans as they cease to be required for defensive warfare.

There is a peculiar cosmopolitanism about the Church of Rome: its official language is Latin; it is a language that is understood and used by all the representatives of the Church, regardless of nationalities, throughout the world; a common or universal language of intercommunication in precisely similar manner as Hebrew is common to Jews throughout all the nationalities of the world. It was this cosmopolitanism, this facility for intercommunication, that spread knowledge, science and the arts simultaneously over the face of Southern and

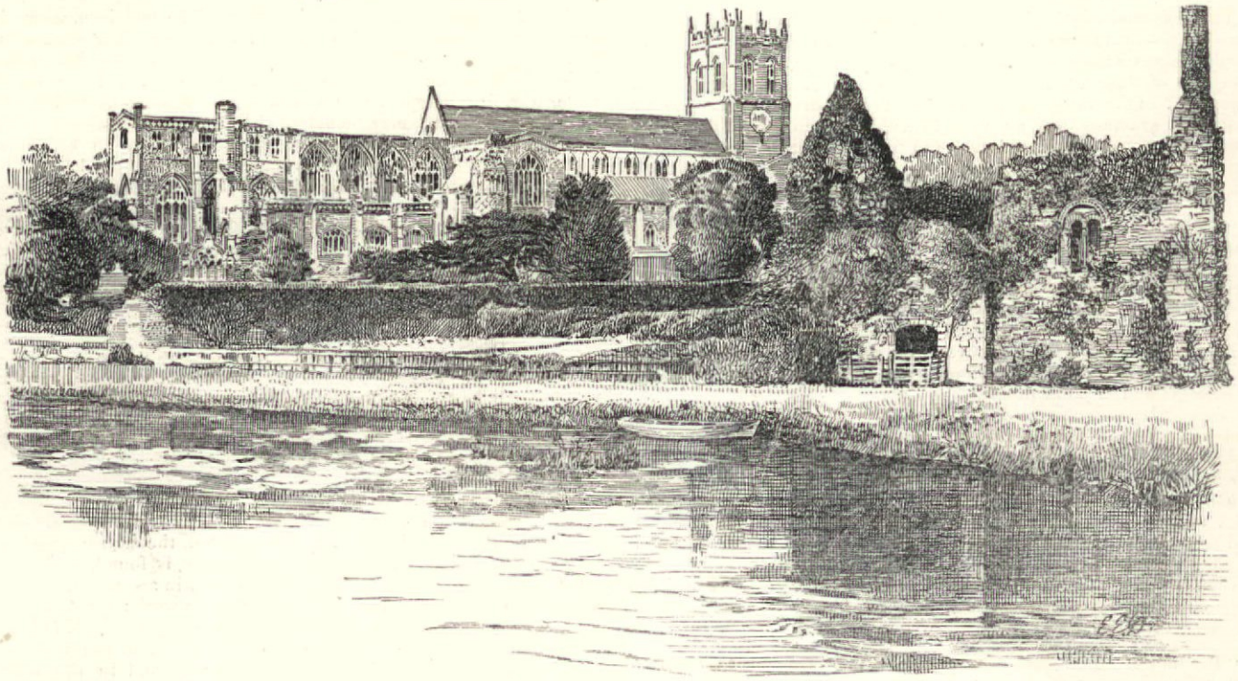
[1] Continued from No. 1328, page 78.

Western Europe; that accounts for the marked uniformity in style of architecture found in all these countries at any one period. As the pronunciation of the Latin tongue varies slightly in different countries, so the architectural expression varies slightly under the influence of climate and the national peculiarities in different countries; but the broad principle is common to all. The advent of the pointed arch marks a contemporaneous epoch throughout Christendom. The Early English is coëval with the "first pointed," or "ogivale primitive," of France.

This period is distinguished not only by the rapid rise of the middle classes, evidenced especially by the assembling of the Commons House of Parliament and the consolidation of public laws, but also by the culmination of the ecclesiastical power in England, which gave so great an impetus to monastic building. This period produced many notable works of ecclesiastic architecture, as for instance, the Abbeys of Dryburg, Netley, Rivaulx, Fountains, Whitby and others, and is also seen in the domestic buildings of the landed proprietors and of those of the mercantile class. The improvements in domestic buildings took place, not so much in the modification of plan or principle as in the general amplification of detail, providing more for the advance in personal and social refinement. All alike proceeded along the path of incessant progress.

privacy; the great log fire was in the midst of the hall, with portable braziers for use in other places; kitchens had the open fire; glass windows were mainly confined to ecclesiastical buildings, framed blinds of cloth or canvas dipped in oil, called fenestrals, being commonly used; furniture was the rough production of the estate carpenter and mostly fixed in its place, and, as Professor Kerr remarks, "spoons and fingers had to serve for forks, and whether between linen sheets in the private chamber of the Baron or under a blanket in the common hall, the sleeper slept without the luxury of a night-dress."

Among the "remains" of this century, Parker gives Temple Farm and Godmersham, Strood, Kent; Aydon Castle, Northumberland; Little Wenham Hall, Suffolk; Charney Basset, and the old Manor-House, Sutton Courtney, Berkshire; Ryball, Rutland; Somerton Castle, Lincolnshire; Stanford and Woodcroft, North Hants; the Prebendal House, Thame; Chipping Norton and Collingsford, Oxfordshire; Gooderich Castle, Herefordshire, etc. The Tower of London was considerably rebuilt by Henry III, and the castles of Manorbere, Kenilworth, Windsor, Raglan, Bodiam and many others were more or less rebuilt, and many scattered manor-houses and granges have portions dating from this century and of clearly marked Early English character.



Christ Church, Hants.

The races had intermarried, and the policy of the Crown was to check the power of the Barons by direct appointment or creation wherever possible, exacting direct personal fealty and homage. During the reign of Henry II the foreign mercenaries were sent away, the reign of the conquering, marauding Norman Baron was drawing to a close, and the Crusades and other foreign wars and travel had enlarged men's minds and improved the manners and customs of the age. The ladies of the period had a certain nobleness of character, the Baroness and her daughters, though not yet very refined and certainly quite unlettered, had begun to consider the great "house-place" of their ancestral "keep" wanting in those conveniences and comforts which developed during the progress of the age. The earlier necessity for security and defence had placed them on the third story in a tower approached by narrow winding stairs. The remoteness of the kitchens and offices impaired their facilities for hospitalities. The growth of these ideas gradually resulted in the abandoning of the keep for family residential purposes and the erection of more suitable apartments and buildings in the court-yard, or inner bailey. We find, therefore, in buildings of the latter part of this century the common hall so situated, to which were attached a "presence" or audience chamber, at one end, and the kitchens and other domestic offices at the other end.

Defensive fortification was still essential; subsidiary towers were built to protect these new buildings, and the old defences of the castle were maintained in efficient fighting condition.

In the new castles built by Edward I in Wales, we find, by comparison, the progress of the times fully illustrated. We find the manor-house with its more spacious chambers, its more expansive accommodation in the family apartments and in the offices, its court-yards surrounded by massive walls and towers as before, and further defended by one or more lines of circumvallation, as may be plainly seen in the works of this period in London and Windsor.

As further evidence of the domestic aspect of the times we may note that ladders and trap-doors were more common than stairs; many of the lofty halls of earlier days became divided by floors into stories; chambers were thoroughfares without much approach to

Portions of the Royal hunting-lodge at Woodstock Chase are of this period, and are inseparably associated with the life and times of Fair Rosamond, her bower being pointed out to this day, though partially destroyed by Cromwell.

THOMAS C. SORBY.

[To be continued.]

PARTIAL USE OF THE DECIMAL SYSTEM THIRTY-FIVE YEARS AFTER LEGALIZATION.[1]

THE process of transition to the use of Federal money, inaugurated by resolutions of the Congress of the Confederation, July 6, 1785, and Aug. 8, 1786, was protracted through the time of our grandfathers, the generation following that which established the money. Kelly's "*Universal Cambist*," whose preface is dated in 1821, thirty-five years after the original legislation, is a standard authority, having had official support. It said of the United States: —

"Accounts are kept here in different ways, but chiefly in Dollars, which are divided into 10 Dimes, 100 Cents, or 1,000 Mills. This is called Federal Money, to distinguish it from the various currencies which were formerly the monies of the United States, and which are still partially retained in domestic traffic. . . ."

The Constitution of Massachusetts said then, and says now, in Chapter VI: —

"III. In all cases where sums of money are mentioned in this constitution, the value thereof shall be computed in silver at six shillings and eight pence per ounce. . . ."

The United States Mint, though it began to coin money in 1793, did not strike many coins except cents, half-cents and half-dollars down to 1820; and coins of the several nations of Western Europe continued in circulation. The Spanish original of our dollar was well known as the "piece of eight," meaning eight "bits" in the

[1] A paper published in *School Science* for December, 1901.

vernacular tongue of the United States, where the Spanish name is less familiar; one bit thus becomes 12½ cents obviously to us, but our grandfathers knew it as of the value expressed according to their long established custom in their different monetary reckonings. John Quincy Adams, Secretary of State, in his celebrated report on weights and measures, also dated in 1821, wrote as follows: —

". . . now, when the recent coinage of dimes is alluded to in our public journals, if their name is mentioned, it is always with an explanatory definition to inform the reader that they are ten-cent pieces; and some of them which have found their way over the mountains, by the generous hospitality of the country, have been received for more than they were worth, and have passed for an eighth, instead of a tenth, part of a dollar. Even now, at the end of thirty years, ask a tradesman or shopkeeper in any of our cities what is a dime or a mille, and the chances are four in five that he will not understand your question. But go to New York and offer in payment the Spanish coin, the unit of the Spanish piece of eight, and the shop or marketman will take it for a shilling. Carry it to Boston or Richmond, and you shall be told it is not a shilling but nine pence. Bring it to Philadelphia, Baltimore, or the City of Washington, and you shall find it recognized for an eleven-penny bit; and if you ask how that can be, you shall learn that, the dollar being of ninety pence, the eighth part of it is nearer to eleven than to any number. . . ."

This was characterized by Mr. Adams as absurd, and justly. Oh, yes — but — by the way, what is it that we are doing, A. D. 1901, thirty-five years after the inauguration by our fathers by the Act of Congress of July 28, 1866, of the change to metric weights and measures? Our rates of postage on foreign-mail matter are by weights in grammes, and we try to look them up in pocket diaries or other common places of reference and find them inaccurately stated by weights in ounces. We turn to the Revised Statutes of the United States, Section 3515, referring to our minor coins, and read:

"The weight of the piece of five cents shall be seventy-seven and sixteen-hundredths grains troy: —"

a circumlocution for five grammes. We have had profile-paper printed with metric subdivisions for its whole length and have measured it off in portions for sale by the yard. Imported paper in rolls of ten metres we have advertised as eleven-yard rolls. These few examples suffice out of many instances of misapplication of units of quantity in business and in publications.

We see the unreasonableness both of the Massachusetts Constitution and of the adherence by our grandfathers, so long after they had established decimal reckoning, to their antiquated book-keeping, which occasioned great inconvenience from the incongruity of the two methods in use at the same time. When our grandchildren look back to 1901, what will they say of our now hanging on to weights and measures that are out of date by consequence of the substitution of the metric units legalized thirty-five years ago?

Consider electricity, whose standards of measurements are fixed upon a metric basis by the law of July 12, 1894. The following is an extract from it: —

"The unit of power shall be the watt, which is equal to ten million units of power of the centimetre-gramme-second system, and which is practically equivalent to the work done at the rate of one joule per second."

Several of the electrical units have become familiar to us through the enormously rapid development of the applications of electricity. This is the case especially with the kilowatt, a commercial unit which we meet with in almost every technical publication we take up; but it has not yet entirely displaced that anomalous old unit, the horse-power (as to which reference may be made to *Engineering*, vol. 63, pp. 245 and 325, for Feb. 19 and March 5, 1897).

Consider the matter of assaying and coinage, in which the metric system is established. It has been used in the Mint for years, and is used in published tables or schedules of coins. The United States subsidiary silver money weighs one gramme per four cents, and thus metric weight is in everybody's pocket. The troy pound has dropped out of practical use. Nevertheless, the troy ounce, incongruous as it is with other weights and measures, still comes in our way sometimes (in other places besides the Massachusetts Constitution).

Consider pharmacy and some other matters connected with chemistry. The "*United States Pharmacopœia*," the reference manual of the apothecary, is exclusively metric. The "*Dispensatory*," the corresponding manual of the physician, has metric values throughout. The use of the metric system was introduced in the United States Marine-Hospital Service about a quarter of a century ago quite thoroughly, and in the army and navy more recently. In practice in civil life prescriptions are to a large and increasing extent written in metric terms; but the mysterious old "apothecaries'" weights and measures (which for sales of candy and popular wares are not used by apothecaries) continue to be used in the prescriptions of some of the older physicians, who in the natural course of events are gradually passing off the stage. Meanwhile, pharmacists have double sets of weights and measures, and employ clerks who understand both, with extra trouble, cost and risk of mistake. In the sale of high-grade chemicals the metric system has been introduced. E. R. Squibb & Sons, of Brooklyn, have used it exclusively for nine years, and the Bausch & Lomb Optical Co., of Rochester, issues a sixty-page priced catalogue "G" of "Chemicals and Reagents" in metric terms, with a conspicuous notice at the top of each page, "Prices of Chemicals are by Metric, *not* Avoirdupois Weight." Much glassware and rubber stoppers are made to metric scale. As to chemical manufacturing, all the tanks in a factory built by the Merrimac Chemical Company, of Massachusetts, for their extensive sulphuric-acid works, were made on metric dimensions, and the Pennsylvania Salt Manufacturing Company have built a large plant entirely upon metric dimensions. The great Solvay Process Company, of Syracuse, makes use of the metric system in every way possible in its works. Drawings to go outside of the works for construction, etc., are not made in the metric system. The Company says it finds no disadvantages, and would be very glad if its entire work could be upon the metric system. That means that as long as people outside cling to ancient weights and measures, so that conformity with them is required of the Solvay Process Company, the Company gets only part of the advantages naturally belonging to its system. Chemical analyses are expressed in parts per million, per hundred thousand or per thousand, corresponding to grammes per cubic metre, per hektolitre or per litre. Grains per gallon are out of date. Nevertheless, in dealing with quantities and consumption of water, there still lingers some use of the United States liquid gallon, a unit long ago abandoned in Great Britain and Canada, distinguished for its lack of connection with other measures or weights, and not ordinarily used in the reading of water-meters.

Consider geodesy and precise levelling. The metric measure has been very extensively used in precise levelling or other work of the United States Coast and Geodetic Survey, the United States Geological Survey, the United States Lake Survey, and the surveys under the Mississippi River Commission. Among other literature from which evidence may be obtained about this, and about working in old measures incongruous with metric, there is an article and discussion on "Precise Spirit Levelling," occupying pp. 1-206 of vol. 45 of the *Transactions* of the American Society of Civil Engineers, June, 1901.

Bulletin No. 26 of the United States Coast and Geodetic Survey, dated April 5, 1893, contained an announcement signed by T. C. Mendenhall, Superintendent of Standard Weights and Measures, and approved by John G. Carlisle, Secretary of the Treasury, from which the following is an extract: —

". . . the Office of Weights and Measures, with the approval of the Secretary of the Treasury, will in the future regard the international prototype metre and kilogramme as fundamental standards, and the customary units, the yard and the pound, will be derived therefrom in accordance with the Act of July 28, 1866. Indeed, this course has been practically forced upon this Office for several years. . . ."

The Treasury Department is the department to which are attached the Mint, the Marine-Hospital Service and the Coast and Geodetic Survey, in all three of which, as above stated, the metric system has been in practical use for years. Incongruity is found, however, in the fact that the Treasury Department continues the use of old weights and measures in other branches of its work; for example, in its Bureau of Statistics, largely occupied with foreign trade (whereas metric units have been introduced to some extent in the Bureau of Foreign Commerce of the State Department and in the section of Foreign Markets of the Agricultural Department); and for another example, in the Customs Service, where there will be special gain in the substitution of the international system, and where its substitution has been repeatedly urged, officially and unofficially.

Consider manufactures. The April, 1900, report of the American Railway Association's Committee on the Metric System enumerated among manufactures in which the metric system has been introduced watches, injectors, refrigerating-apparatus, screw-cutting lathes, scales, drills, gauges, astronomical and physical instruments, measuring implements and draughtsman's supplies. A very large number of manufacturers have had some call for the application of metric measurement for goods for export, if only on a small order; and goods of widely diverse character are among the metric manufactures. We have exported to metric countries a great deal of ordnance and machinery for manufacturing ordnance, and rapid-firing guns have been designated by their calibre in millimetres. The Baldwin Locomotive Works' illustrated catalogue of narrow-gauge locomotives has printed on its title-page, "Adapted Especially to Gauges of 3 Feet 6 Inches, or One Metre," and on each of the sixteen pages (108–38), on which are tabulated various types of locomotives, has printed conspicuously, "Gauge, 3 Feet 6 Inches, or One Metre." The Library Bureau, of Boston, has cards and cases made of exact metric dimensions. In the *Electrical Review* (New York) for June 22, 1901, Geo. H. Draper says: —

"There is no first-class shop in America that will not undertake to build machinery according to metric measurements, and many of them are at the present time compelled to build stock forms of machinery in measurements of this system in order to be able to compete for trade in foreign countries where the specifications are given in round metric terms."

The following sentences are quoted from the *American Manufacturer*: —

"The metric system is making some headway among American manufacturers engaged in the export trade. This is especially true of machinery builders. It will continue to make headway according to the increase of our exports. . . .

"There are firms that have adopted the metric system for their export business. They do not seem to be suffering from the effects of having two sizes of templates and dies for their plants. They are filling orders for export and are teaching their workmen the use of the metric system in so doing."

The incongruity of having two sizes, whether there seems to be suffering from the effects or not, continues until the superseding in domestic trade also of old weights and measures by metric. A similar remark may be made in regard to United States importations of bottled goods, textiles and other manufactures from foreign countries where the metric system is in use.

Consider bodily measurements, etc. The stature and strength of athletic young men in the colleges in different parts of the country are recorded in metric units and are published; but sometimes the newspapers, instead of recognizing the kilos, call them "points." Dimensions of statuary, etc., have been given metrically in the reports of the Boston Museum of Fine Arts regularly for many years. There is great convenience in measuring the clothes, as well as the body, in centimetres, not requiring fractions; and among men's furnishing goods some suspenders may be found with the length marked upon them in centimetres; but there remains in principal use for the measurements of tailors and dressmakers, and for sizes of such things as gloves and hats, the old unit with the ubiquitous fraction.

Consider applications of science. The metric system has been thoroughly adopted for scientific research upon all subjects and for the diffusion of scientific knowledge by publications and educational institutions. The extent of its use for instruction, laboratory supplies, apparatus, etc., is enormous; yet when scientific knowledge is utilized in technical work or for commercial purposes it often happens that old units of measurement are employed; so we have the incongruity of preaching one thing and practising another, of producing certain effects with one measure in investigation and with another measure in business. Such complications are now a characteristic feature in our literature, the discussions of our professional organizations, reports of committees of research, periodical publications, or books of the day. Similar complications are common in shops, offices and practical work, a fact so familiar as to require little illustration. Fineness of sand is expressed by the millimetre, and fineness of the sieves and screens for it by the number of meshes per inch. It is by the cubic centimetre of water that the number of bacteria are reckoned in biological examinations, but, rather than say so, men otherwise intelligent have sometimes disguised it for the popular mind as "thimbleful." Opticians have adopted metric measure, and, besides whatever else they have done in regard to their apparatus and accessories for microscopy, etc, they have a metric basis for expressing the power of lenses of spectacles. Their "dioptrics," depending on the focal length in metres, are found in the optician's price-list; yet it is not uncommon to express the diameters of lenses in old measure, which may be found even in the same catalogues that give generally the metric system.

It is needless to marshal further evidence. The cutting off of the dog's tail is by centimetres, so that the tail may continue in some measure to wag the dog as long as he likes to have the operation protracted.

BOOKS AND PAPERS

FEW people realize the advance which has been made within the last twenty years in the matter of public water-supply, and sanitarians and engineers, to whom the improvement is almost wholly due, would deserve the gratitude of mankind for this work, if they had never done anything else. On the other side of the ocean, much greater progress has been made than here. Twenty or twenty-five years ago, it was not only disagreeable, but often dangerous, for an unacclimated tourist to drink the water supplied to the cities of Paris, Liverpool, Venice and Naples, to say nothing of smaller towns. Now each of these cities is abundantly supplied with water of a purity which would make almost any American city envious. Paris has its special supply of spring-water; Liverpool has brought water from the mountains of Wales by a submarine tunnel; Venice has replaced its cistern-water by an ample supply from the mountains of the mainland, and Naples has just finished an aqueduct, some twenty miles long, which brings the clearest water in profusion from springs in the mountains. To those elderly tourists who remember the pangs which, not very many years ago, followed indulgence in the drinking-water then supplied to these places, the change is very striking; and more than one such person, probably, has wished that similar regeneration might come upon Philadelphia, Boston, and other towns of our own. In this compact and convenient book [1], the third edition of a work which first appeared only five years ago, Mr. Thresh gives an immense amount of valuable, and thoroughly modern, information in regard to what might almost be called the new science of gathering, purifying, preserving and distributing both public and private water-supplies. As readers of technical books know, English works of the kind often contain an inordinate amount of padding, in the shape of accounts of the engineering practice of the ancient Romans, and long descriptions of constructions of the period of George the Fourth; and it may relieve the minds of such persons to know that Mr. Thresh has found enough matter of interest and importance to fill his work completely, without any archæological or historical digressions.

Beginning with the necessary observations on the sources and properties of water, the book continues with an examination of public water-supplies as they actually exist, including the sources of contamination to which they are exposed; and here we find a concise, but most instructive, review of the cases of contamination by microscopic animals and plants, so many of which have been recently reported, and of the measures, unsuccessful and otherwise, which have been taken to remedy the trouble. Next to this we find a chapter of great importance, on the "self-purification of rivers," in which the results of modern investigation are well summed up by the author, who says, "The question in which we are interested, therefore, is, not whether a fouled river-water may regain its pristine appearance of purity, but whether it can ever again become absolutely safe for drinking purposes. Ordinary observation enables us to answer the first question in the affirmative; all the researches of chemists and bacteriologists, since the days when the Rivers Pollution Commissioners first experimentally studied this subject, have failed to answer the second." On the whole, Mr. Thresh thinks that the preponderance of evidence is "decidedly on the side of those who uphold the theory of self-purification"; and the most important opinion on the other side seems to be that of the Massachusetts State Board of Health, which says that "no river is long enough to purify itself." In the approaching struggle between the cities of St. Louis and Chicago, in regard to the pollution of the Mississippi River by the Chicago Drainage-canal, this matter will, presumably, be thoroughly discussed to the advantage of mankind.

After this, we find discussions of the sources of public and private water-supply, and of the modern modes of storage, which, as all architects and engineers know, have been greatly modified within the past few years; and these, with some observations on distribution, complete an extremely useful little book.

[1] "*Water and Water-supplies.*" By John C. Thresh. Third Edition, Revised and Enlarged. Philadelphia: P. Blakiston's Son & Co. 1901. Price, $2.

NOTES & CLIPPINGS

FORGED PICTURES. — The statement by Mr. Sidney Cooper, R. A., that of 287 pictures purporting to be by him no fewer than 255 had proved on examination to be frauds and the signatures forgeries has naturally aroused widespread interest. Unfortunately for the artist, the imitation of his signature on a painting is not forgery in the eyes of the law. To constitute forgery the thing imitated or falsified must be connected with a document or a writing. Consequently it is a common thing for pictures to be copied and the signature of the original painter boldly inserted. Sir Lawrence Alma-Tadema said recently: "I have been chairman for three or four years of a committee which has been striving to amend the laws of artistic copyright. We got as far as introducing a bill, but the House of Lords cut out the most important points as affecting artists. They knew nothing of the subject, and Lord Thring went so far as to make the strange statement that an artist's signature on a painting was not a signature but a part of the painting itself. It is a scandalous state of things that a painter is not protected in his copyright. The purchaser is protected, but not the painter." Mr. S. J. Solomon, R. A., had much the same story to tell — he is also a member of the Artistic Copyright Committee — and drew attention to the enormous number of piracies and forgeries on the Continent. "There are literally thousands of Corots," he said, "which have never been within a mile of Corot's studio." The chief art-dealers of London are on the side of the artists in this matter. At Messrs. Agnew's, in Bond Street, a hearty agreement with Sir L. Alma-Tadema was expressed, and it was stated that it was also as much in the interest of the purchaser as that of the artist that the copyright law should be amended. At Messrs. Graves's galleries in Pall-Mall it was stated that copies and imitations were regularly manufactured in this country as well as in France and elsewhere. — *London Daily Mail.*

TWO THEORIES OF WHITE LIGHT. — In an article in *Comptes Rendus*, by O. M. Corbino, two opposite views of the constitution of white light are stated, and a theoretical decision between them, based on known experimental results, is arrived at. Gouy maintains that the constituents of the spectrum of white light are the sinusoidal components of a single complex vibration, and are capable of mutual interference; while Carvallo regards the separate radiations as completely independent, and therefore incapable of interference with one another. The latter view is supported by the spectroscopic observation of beats produced by two pencils of white light, one of which is slightly altered in period by means described elsewhere by the author and by Righi. In the case of monochromatic light, alternations of light and darkness are observed; in the case of white light, movable fringes are seen. In the latter case the fringe system should exhibit no alteration when the change of period is effected, if the hypothesis of Gouy is true. The fringes are, however, seen to move, and hence it follows that interference takes place only between radiations which had the same period in the source before the alteration of period, and not between those which, originally different, have been brought into coincidence of period. Hence, the second hypothesis is accepted. — *N. Y. Evening Post.*

A REPENTANT VANDAL. — At Mount Vernon there is the largest army of "spotters" on the lookout for vandals; and it is more necessary there than anywhere else, for Washington's home would be easily despoiled. The visitor pays a quarter admission, and the money goes to pay his watchers. There is one thing in the house that strikes the notice by its contrast with the prevailing simplicity. It is the carved mantelpiece of Carrara marble in the dining-room. One who is not a vandal cannot gaze upon it without anathematizing the whole race of relic-seekers. Even with watchers in every room some individual managed to "get in his work" and get off the head of a galloping deer in the centre of the group. The animal remained headless for months. Then one day the head came back in a little box. It was post-marked Paris. An accompanying note stated: "It did not occur to me, in my own country, where everything is so well cared for and preserved, the outrage that it is to mutilate historic places for relics. Here in Europe nothing is preserved; everything is marred and chipped and broken by travellers like myself. I return herewith," etc. The letter was anonymous. When the head was put back the glue stained the marble, and the milkwhite deer has a yellow streak around his neck. — *N. Y. Tribune.*

FINE FOR COUNTERFEITING OLD TAPESTRIES. — The Paris Court of Appeals has given its decision in the case of tapestry-dealers who had falsified their wares so as to resemble antiques. Charlaunes, of Paris, and Sauvageot, of Troyes, had sold these "doctored" aubussons to Mme. Lemaitre, of Epernay, and for this offence the Seine tribunal condemned them some days ago to six months' imprisonment, $200 fine and $1,400 damages. On appeal, the sentence has been confirmed, and the damages increased to $2,600. — *Exchange.*

DAMAGE DONE BY LOCOMOTIVE SPARKS. — Damage to property through the ejection of sparks by locomotives is an old grievance of those holding property adjacent to railways. The question has, however, been brought rather prominently forward of late by one or two serious fires and by correspondence in the *Times* and in the columns of the *Engineering Press.* Under the present state of the law, railway-companies are not responsible for fires caused by their locomotives, so long as the best known appliances are fitted for preventing, as far as possible, the escape of sparks from the chimney. A bill was recently introduced into Parliament to alter these conditions, but failed to pass. It will, however, probably be brought forward again next session. The case of Hipkins *vs.* the London and Southwestern Railway Company, recently tried and settled in favor of the defendants, produced a good deal of interesting evidence on the part of railway-engineers, both English and American. For the plaintiff, whose field of corn was burned, it was held that if the engine had had a netting or grid below the base of the funnel dangerous sparks could not have been emitted. The arrangement is common in America, but it has its drawbacks, inasmuch as it checks the draught and thus reduces the efficiency of the engine. Partly to get over this the American engineers prolong the smoke-box in front of the boiler so as to get in a bigger netting and thus give a larger area for draught. The somewhat unsightly extension of the boiler structure beyond the chimney, which adds so much to the grotesque appearance of American locomotives, is accounted for in this way. — *London Times.*

CONTROLLING THE SHIFTING SANDBANKS ON CAPE COD. — The Harbor and Land Commission of Massachusetts is trying an experiment, which, if successful, will attract attention outside of the Commonwealth and will be adopted by other States along the coast which are similarly afflicted. This affliction is the shifting of the sand by the wind on Cape Cod and is a constant annoyance to those who live or spend the summer on "The Right Arm of Massachusetts." Provincetown, situated on the extreme end of the Cape, has been the greatest sufferer, and a fine pine-grove, the pride of the town, which was set out a few years ago, is threatened with swift destruction by the blowing sand. The remedy which is under trial is simple, and consists of planting beach grass along the ocean side of the Cape. A few months ago a large amount was transplanted from another part of the State, where it was not needed. It is hoped that the grass will spread, and it is said that the roots will hold the sand better than anything else that is known. The sand-dunes of Cape Cod grow at the rate of about two feet a year, and the force of the sand driven by the wind is so great that the glass in the lanterns of some of the lighthouses becomes completely ground in a short time and frequently has to be renewed. — *N. Y. Tribune.*

SOUTHERN PINE OUTPUT. — Secretary George K. Smith of the Southern Lumber Manufacturers' Association, in his annual report before that body, gave out statistical information which will be of interest to manufacturers of lumber throughout the United States. An average of 160 mills for the twelve months of the year, embracing 1,759 firms, cut 1,992,602,851 feet, while shipments for the same time were 2,090,120,270 feet. This is an increase of 200,000,000 feet in the output as compared with the previous year, or 11 per cent, while shipments were in excess of those of 1900 by 344,000,000 feet, or 20 per cent, thus reducing stocks held 100,000,000 feet, or about 10 per cent. These figures apply to the yellow-pine lumber situation. With regard to white-pine, there was a reduction, through excess of shipments over cut, of 200,000,000 feet, or 13 per cent, in the visible supply up to Dec. 1, and an increase in output of 119,000,000 feet, or 5 per cent. — *Exchange.*

TROLLEY-OPERATED FIRE-ENGINES. — The Chief of the Fire-department at Rouen proposes to make use of the electric trolley-wires which extend to so many parts of the city, and in which power is or can be always ready for use as a source of power for driving the pumps of fire-engines where the fire occurs in the neighborhood of electric tramlines. The fire-engines will be fitted with electric-motors instead of steam-engines, and connection will be made to the trolley-wire or to the trolley-feeder in the immediate neighborhood of the burning building. The arrangement should save valuable time, especially during that important first fifteen minutes, since there will be not even the necessity of getting steam up from banked fires. If also the connection to the electric tramway service is made at one of the feeder-pillars, as can easily be done, the tramway service should not be interfered with. — *London Trade Journals' Review.*

TRANSPLANTING TREES FOR THE ST. LOUIS FAIR. — Probably the largest contract ever let in this country for the transplantation of big trees is that just entered into for the World's Fair in St. Louis. The site of the World's Fair is Forest Park, in which there are many large trees. Actuated by a desire to preserve as many as possible of the trees and to have their shade in the broad avenues of the Exposition, the Director of Works will have 700 trees, each 12 to 18 inches in diameter, lifted and replanted where they will remain permanently. Special machines will be used and the transplanting will be done while the trees are dormant and the ground is deeply frozen, so as to carry as much earth with the roots as possible. Very great care is required for a successful operation, and the trees will be given the best care and attention, in order to assure their thrifty growth. The trees are principally maples and elms. — *Boston Transcript.*

CARPEAUX'S MODELS. — The Paris *Chronique des Arts* announces the gift to the city of Paris by the widow of the sculptor Carpeaux of a large number of important studies found in the master's atelier after his death. Especially interesting are the monumental group erected to the memory of Maréchal Moncey, and the studies for the famous figures of dancing nymphs in white marble on either side of the main entrance of the Opera-House. These figures were criticised thirty years ago as too bold, criticism taking the shape one night of a shower of ink, an act which aroused a stormy controversy that lasted for months, Napoleon III was, however, a firm friend of Carpeaux, and the statues remained. Carpeaux's study for a monument to Moncey was not intended for execution, as he was a member of the jury that awarded the prize, but simply as an expression of his own ideas upon the subject.

THE SPEED OF SOUND. — The last determination of the speed of sound has been made by Mr. A. Leduc, who finds that the rapidity of propagation of sound-waves through dry air at 0° C. (= 22° F.) is 1,088.58 feet per second. — *Comptes Rendus*, December 26, 1898.

NOTES AND CLIPPINGS. 40

THE new Commission for the improvement of the city of Washington has placed on view, as promised, its preliminary plans and models for the scheme which it proposes. They are, certainly, sufficiently radical to suit the most ardent lover of reform, but it can hardly be said that they are too much so, in view of the end which it is desired to accomplish, and which can be accomplished more easily and cheaply now than in the future. Practically, the plan contemplates condemning the whole territory between Pennsylvania Avenue and the river, for a distance of a mile or more, removing the present buildings, and remodelling the streets. From the Capitol is to extend westward to the river a "boulevard," bordered by parks, something after the fashion of the Champs-Elysées, in Paris. These parks are to form the site of public buildings, which will stand isolated in them, as the palace of the President of France stands in its own garden adjoining the Champs-Elysées. The western end of the "boulevard" is to be continued by a monumental bridge across the river in a straight line toward Arlington. It is quite possible for such an avenue to have a wearisome straightness, and the Commissioners, although they did not think it advisable to curve it in plan, have, with true artistic feeling, provided variations of level in it, which, without interrupting the beautiful vista toward the Capitol at one end, and the heights of Arlington at the other, will greatly relieve its monotony. Between the White House and the Monument the present uninteresting open space, containing some irregular ponds, is to be transformed into an elaborate garden, or small park, adorned with bridges and terraces, and surrounded by public buildings. Beyond this, a wide driveway is to extend along the river-front, from the Arsenal grounds to Rock Creek, then turning, and following the valley of Rock Creek to the Zoölogical Park and the Soldiers' Home. As a portion of the river-front is occupied by warehouses and steamboat-landings, it is proposed to carry the new driveway over this portion by a viaduct, so that the traffic between the landings and the main part of the city can be carried on without interfering with pleasure driving. Although the execution of the plan will be costly, it need not be extravagantly so. The Government already owns a considerable portion of the land included in the scheme, while, of the rest, much is at present of little value. It can hardly be questioned that the southwestern part of the city, sloping from Pennsylvania Avenue to the river, is susceptible of far more artistic treatment than any other portion, and it is none too soon to take it in hand, and begin its transformation into what would be a piece of municipal landscape architecture of unexampled magnificence.

MUCH interest has been excited by the question of the appointment of the successor to the late Edward Clark, Architect of the Capitol at Washington. The laws of the United States provide that this official shall be "a professional architect," which is certainly a reasonable requirement, but it seems that the principal clerk in the office of the late Mr. Clark, who, as we understand, does not claim to have had a professional training, but who has shown great efficiency in the prosecution of work directed by his chief, and ingenuity in devising ways of accomplishing results, is likely to receive the appointment. Mr. Woods is popular in Washington, where personal popularity counts for a great deal, and is, undoubtedly, on excellent terms with the architects who frequent Washington society, as well as with their friends; so that they deserve to be honored by the profession and the public for having, in most cases over their own signature, and at the risk of offending their personal acquaintances, called attention to the requirements of the law, and to their obvious inapplicability to Mr. Woods. For the moment, there seems to be a feeling in Congress that the general professional protest against the appointment has something exclusive and unfair in it, and it has been proposed to change the law, which Congress and the President can, of course, do, so as to permit the appointment of a layman as Architect of the Capitol, joining to him, on occasion, a consulting architect of recognized professional standing; the idea being, of course, to open the way for the appointment of Mr. Woods.

WE need hardly say that this would be a most deplorable proceeding, and it is to be hoped that the public will support the profession in earnest deprecation of any legislation of the sort proposed. We have a high opinion of Mr. Woods, personally, and the best wishes for his advancement, but this cannot blind our eyes to the fact that the Architect of the Capitol is entrusted with the artistic as well as the scientific care of what we feel to be one of the most beautiful buildings in the world, and the highest professional accomplishment that the country can produce is not too high to be devoted to its service. It is true that Congress proposes to appoint a "consulting architect," to advise, whenever he happens to be called upon, in regard to artistic matters concerning the Capitol; but the profession is very familiar with consulting architects, and with the real influence which they exert on the building-work with which they are supposed to be concerned; and we venture to say that every member of it who has acted as consulting architect, or has been associated with one, will agree with us that such an official would be powerless to prevent the destructive tinkering with the Capitol which seems to form the mania of so many people, in and out of office, in Washington. It is not many months, for example, since the newspapers informed us that huge "pylons" were to be set up somewhere about the entrance to the Capitol; and not a year passes without the promulgation of some monstrous scheme, often with very powerful backing, for making our beautiful building ridiculous. Even if a "consulting architect" were "consulted" about these precious schemes, which he rarely would be until their originators had made their success secure, his authority, as a mere adviser, would be insufficient to prevent their execution, and the division of responsibility would do more than anything else to destroy the possibility of the resolute and intelligent control which alone can save the Capitol from disfigurement.

THE local Associations of Master Builders are quite generally adopting a code of ethics, by which the unwritten law, requiring general contractors who ask for or receive sub-bids to employ the lowest sub-bidder in case the contract is awarded to them, is made into a written law, with a penalty attached to its violation. As the rule is obviously founded on courtesy and justice, no one will regret to see it enforced by a measure which should do much to prevent the disappointments and recriminations that so often follow the award of important contracts; but architects have also an important interest in the award of sub-contracts, and they should be more careful than ever not to let the control of the selection of sub-contractors slip from their hands. It is common in building-contracts to stipulate that neither the whole nor any portion of the contract shall be sublet without the written consent of the architect; and every architect knows that this restriction is absolutely essential to the proper execution of the agreement. No matter how honest or popular a mechanic may be, he cannot carry out satisfactorily work in which he is inexperienced;

Entered at the Post-Office at Boston as second-class matter

and architects continually have sub-contractors proposed to them who are not only inexperienced, but, in many cases, of very doubtful honesty. The new code of builders' ethics provides that a principal contractor who receives and opens a bid, no matter who it may be from, is bound to give the same consideration to it, and to the party submitting it, as to those submitted by his special request, and it is evident that a busy or good-natured contractor is likely, under such conditions, to find himself bound to sub-contractors whom he does not wholly approve. It has been the rule in these cases for the general contractor to shelter himself behind the architect, and to get rid of the questionable sub bidder by telling him that the architect would not accept him; but, under the new code, this will not be so easy, as, although a clause in the contract requiring the architect's approval of all sub-contractors is, of course, paramount to any regulations which the builders may adopt among themselves, an aggrieved sub-bidder, by appealing to the authorities, and demanding damages, may give a great deal of trouble to all parties concerned. The simplest method of meeting the difficulty is one which has already been adopted by the most experienced architects, consisting simply in a demand that each principal contractor shall submit to the architect a list of the persons whom he intends to invite to make sub-bids, to be revised and approved by him before the invitations are issued. In this way the principal contractor escapes the necessity of offending his acquaintances, by casting the blame for their exclusion on the architect; and, as the latter exercises his right of approval before the invitations are sent out, there is no chance of trouble from a sub-bidder whom he has been obliged to reject after the sub-bids were in. The better class of general contractors accede readily to this arrangement, which protects them against misunderstandings with their sub-bidders, besides doing much to save them from being saddled with the responsibility for incapable or dishonest sub-contractors; and it is only necessary to see that it is made at the beginning of the figuring to carry it through successfully.

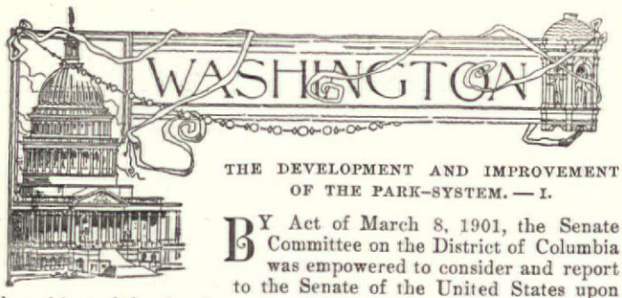
JOHN APPLETON BROWN, one of the most distinguished of American landscape-painters, died a few days ago, at the age of fifty-seven. Although Mr. Brown had long devoted himself entirely to landscape, he began his career as figure-painter, sharing a studio in Boston, when very young, with B. C. Porter, since greatly distinguished as a portrait-painter. Finding that his work did not satisfy his ambitious ideals, he gave up his studio and went to Paris, where he studied in the Louvre, and with Lambinet. He returned to Boston for a few years, but, immediately after his marriage, went to Paris again, where two of his pictures were accepted at the *Salon*. His subsequent life was spent partly in Boston and partly in New York, with an occasional vacation in Europe.

MAYOR LOW of New York has appointed, as the members of the Board of Building Examiners, whose duty it is to hear and decide appeals from rulings of the Building Department, Messrs. A. F. D'Oench, of the New York Chapter of the American Institute of Architects; Francis C. Moore, of the New York Board of Fire Underwriters; Warren A. Conover, of the Mechanics' and Masons' Exchange; William J. Fryer, of the Society of Structural Iron Manufacturers; Cornelius O'Reilly, of the Real Estate Owners' and Builders' Association, and Edward F. Croker, Chief of the Fire Department. We need not say that, except the last two, all these gentlemen have long been eminent in the science of construction, and most of them have had experience in the duties committed to them. Mr. O'Reilly is well known as a man of ability in his own province, and Mr. Croker bids fair to be a worthy successor to the earnest and able Bonner; so that the new Board of Examiners will have the confidence of the professions most interested.

AN attempt is to be made to complete the half-finished Hudson River tunnel, and a committee has been formed to float stock and bonds of a new company, formed, we suppose, by reorganizing the old one. Five per cent first-mortgage bonds are to be issued, to the amount of seven million dollars, and the rest of the capital is to be represented by three and one-half millions preferred six per cent stock, and five millions of common stock. It is said that two and one half millions of bonds will be reserved for the completion of the second tunnel, if that should be considered expedient. It is not stated whether all existing indebtedness is to be paid off, so that the new mortgage-bonds will really hold the tunnel and terminals as security, or whether, as in the case of certain railway reorganizations, the property is already mortgaged for all it is worth, and the new company merely proposes to issue seven million dollars' worth of bonds secured by an equity of no actual value whatever, but these matters will undoubtedly be explained in time. Meanwhile, it is a satisfaction to know that there is a prospect of the completion of this great work, whatever may be the financial aspects of the affair.

THE French Minister of Fine-Arts, who has, as our readers know, secured the admission of women to the Paris School of Fine-Arts, where one of them, Mademoiselle Morgan, is winning distinction in the Department of Architecture, has presented for the approval of President Loubet a much more radical measure, by which "all artists, of either sex, aged from fifteen to thirty years, whether pupils of the School of Fine-Arts or not, provided they are French, may compete for the Prizes of Rome, after passing through two preliminary examinations." It remains to be seen whether the President will sign the decree in this form, but, as a thoughtful and unprejudiced man, familiar with the wishes and needs of the provinces, it seems very likely that he may approve a measure which will not only encourage women by opening to them the highest honor which France has to bestow on students of art, but will do much to remove the reproach which the provincial cities have long cast upon the national system of instruction in art, that its benefits were restricted to those who lived in Paris, or whose families could afford to send them there. In France, where art is looked upon as perhaps the noblest of all careers, and where boys who have shown character and talent are not unfrequently sent to Paris, and maintained there during their course at the School of Fine-Arts, at the expense of their native town or village, this is a very serious matter. It has often been proposed to remedy the trouble by establishing branches of the Paris school in the principal provincial cities; but this would be a very costly proceeding, and the atmosphere of such a provincial school would not be quite the same as that of Paris; and the proposition of M. Leygues, by allowing students outside of any official school to compete for the great prizes of the Paris School, is likely to please the provincials quite as much as the establishment of local schools, while it will cost nothing to carry it out. It is, perhaps, premature to speculate on the influence of such a measure, supposing it to be adopted, on the development of French art, but it seems obvious that it would be immediately followed by the opening, in all the principal provincial cities, of *ateliers*, intended expressly to prepare pupils for the competitions for the Prizes of Rome. There are many accomplished architects, to say nothing of painters and sculptors, in France, outside of Paris, and nearly all of these would do their best to prepare pupils for a contest, victory in which would cover their teachers, as well as themselves, with glory in their own community. In some ways, the teaching in these provincial *ateliers* would be more personal and individual than it can be in busy Paris, while the pupils, taken from families who hesitated to send their boys and, still more, their girls, away to Paris, would be, undoubtedly, as intelligent as those of the official school, besides being less distracted by the excitements of the capital; so that we might expect to see, not only an occasional Prize of Rome winner from a remote private *atelier*, but, in such winners, an originality of talent which would be of great value. Notwithstanding all that is said about academic formalism and routine in the French teaching of art, there is no place where artistic originality is more quickly recognized or more highly prized than in France; and if the new system, whenever it may be adopted, should lead, as seems probable, to the introduction of new ideals and thoughts in the practice of painting, sculpture and architecture, no one will rejoice more sincerely than the great artists who make the Paris School of Fine-Arts what it is.

ONE of those miraculous dispensations which so frequently afflict the virtuous has been experienced in Detroit, where four buildings recently "fell into a heap without a cause," demolishing in their fall about a hundred and fifty thousand dollars' worth of goods stored in them. "Experts," we are told, have examined the ruins, but are unable to find any reason for the catastrophe, and it seems to be quite obvious that Providence alone is to blame.



THE DEVELOPMENT AND IMPROVEMENT OF THE PARK-SYSTEM. — I.

BY Act of March 8, 1901, the Senate Committee on the District of Columbia was empowered to consider and report to the Senate of the United States upon the subject of the development and improvement of the entire park-system of the District of Columbia. The Committee was further empowered to sit during the recess and to employ at its discretion expert assistance, the expense of such investigation to be paid from the Contingent Fund of the Senate.

The Committee has now submitted its report, which has been unanimously adopted. The Report begins by saying that the District of Columbia was created to be the seat of government of the United States and Washington was laid out as distinctively a capital city. The first consideration in its planning was the location of the public buildings and the grounds relating to them. In determining these locations each site was selected in reference to every other site. The lines of communication between the various Departments were carefully studied, and care was taken to provide not alone for convenience, but also for beauty and dignity.

The original plan of Washington, having stood the test of a century, has met universal approval. It is the departures from that plan that are to be regretted and, whenever possible, remedied.

The Report then goes on to take up the problem in detail. The area added by the reclamation of the Potomac Flats must be treated as an extension of the Mall and Monument grounds, while that part lying as an island in the river may be individually treated. Of the 170 acres in the valley of Rock Creek, acquired by Congress in 1889, and now the Zoölogical Park, and of the later purchase of 1,600 acres running north on Rock Creek to District line and now known as Rock Creek Park, the Report says simply that there are some roads, but a need of landscape treatment.

The "flats" above navigation on Anacostia Creek, 1,100 acres, should on account of the city's health and the needs of its north-eastern district be reclaimed and made a water-park. It should now be decided either to fill or park the valley of Rock Creek from its mouth to the Zoölogical Park.

The parks need development, enlargement, and to be properly connected. The existing squalor of their approaches and entrances should be cured.

Attention is called to the function of our parks in adding dignity to the public buildings and suitable connections between them aside from the matters of health and pleasure.

It is historically noted that the plan prepared under the direction of Washington and Jefferson studied the relations, in an artistic sense, between the White House and the Capitol, and the reciprocal relations of buildings throughout the city; the question of vistas and axes; sites for monuments and museums, parks and pleasure-grounds, fountains and canals. All these things were thought of by Major L'Enfant working under the direction of the first President and his Secretary of State. Great models were studied. Washington and Jefferson were familiar with the art of landscape. L'Enfant was a man of position and education and an engineer of ability. He was doubtless familiar with the great works of Le Nôtre, the master of formal landscape art.

Mr. Jefferson lent Major L'Enfant from his private library plans of Paris, Amsterdam, Frankfort, Carlsruhe, Strasburg, Orleans, Turin, Milan and of other European cities.

The plan for Washington has suffered some sad changes, but these may be remedied and it brought back to the intention of the founders. It is now time to consider and to adopt a plan which will make of Washington "the most beautiful capital city in the world."

Thus broadly and bravely is the issue set forth.

Allusion is made to the Institute's part in bringing about the Senate's action, and it is stated that the appointments of Daniel H. Burnham, of Chicago, and of Frederick Law Olmsted, Jr., of Brookline, to prepare plans were made at the instance of the committee named by the Institute to confer with the Senate Committee. Charles F. McKim and Augustus St. Gaudens became members of the Park Commission so-called, at the request of the original nominees.

The work of the Commission was at once broadened by their being consulted as to public buildings and memorials already under consideration. The officials, and many others interested, have worked cordially to assist them. The action of the Pennsylvania Railway, through its President, Mr. Cassatt, in agreeing to relinquish their grant upon the Mall — their title to which the Report says is not to be questioned — and to remove their tracks and yards and station, is most important. The road agrees to a union station — with the Baltimore and Ohio — upon a site determined and provided by legislation, with some compensation for the increase of expense involved and upon condition that the approaches to the new site be made worthy of the building erected.

This union station will be on Massachusetts Avenue, facing the Capitol, but not too near. It will be of white marble and of Classic architecture, some "100 feet wider than the Capitol" and "to be superior to any structure ever put up for railway purposes."

The station will front upon a semicircular plaza 600 feet wide, where bodies of troops and civic organizations, debarked for public spectacles, may form.

It will be the "great and impressive vestibule to Washington."

The Report adds here something which is pleasant reading. It is that the President of the Pennsylvania Railway has considered this question from the standpoint of an American citizen, saying that he appreciated the fact that if the Congress intended to make the Mall what the founders of the city intended it to be no railroad should be allowed to cross it. The greatest obstacle to a proper treatment of the problem being thus removed, the Commission entered upon the preliminary surveys and studies.

It was determined that the climatic conditions of Washington, with its usual intense summer heat enduring through four months or more, demand alleviation by means of parks and recreation grounds.

Historical allusion is made to the building of fountains in Rome by the Emperors and the Popes, to the bringing down of living streams from the hills to every quarter of the Eternal City, placing fountains and jets everywhere, cascades, "beautiful jets of water now flung upward in great columns to add life and dignity even to St. Peter's; or again gushing in the form of cascades from some great work of architect or sculptor; or dripping refreshingly over the brim of a beautiful basin that was old when the Christian era began. The Forum is in ruins, basilicas and baths have been transformed into churches, palaces have been turned into museums; but the fountains of Rome are both omnipresent and eternal."

The need of fountains in Washington is dwelt upon; and to set playing what we already have, all together, would not use as much water as the famous fountains of Trevi or St. Peter's. At the château of Vaux-le-Vicomte, near Paris, Le Nôtre built cascades, canals and fountains, using five million gallons of water daily. The fountains of Versailles remain the delight of the French people. L'Enfant appreciated the worth of water-decoration and recommended its lavish use here. The Commission adds public baths and gymnasiums, and notes the facilities for fine bathing-beaches. As to the location of public buildings, the following is advised: —

"1. Only public buildings should face the grounds of the Capitol.

"2. That new Department buildings may well be located so as to face Lafayette Square;

"3. Buildings of a semi-public character may be located south of the present Corcoran Art Gallery, fronting on the White Lot and extending to the park limits;

"4. That the northern side of the Mall may properly be used by museums and other buildings containing collections in which the public generally is interested, but not by Department buildings.

"5. That the space between Pennsylvania Avenue and the Mall should be occupied by the District buildings, the Hall of Records, a modern market, an armory for the District militia, and structures of like character."

The Mall was meant to connect the two great buildings of the Nation, the Capitol and the White House, with a broad parked avenue and to serve as a grand setting for these buildings. This idea should be restored and carried out.

The present plan brings the Washington Monument into the Capitol vista by means of a broad grassy *allée*, bordered by formal bosks of trees.

Behind these trees show the white marble buildings of the scientific bureaus, museums and like buildings. Walks and driveways shaded by elms run east and west. The streets running north and south are carried through this avenue on the surface level.

From the Capitol to the Monument is about one and a half miles. A mile or so westward of the Monument the reclaimed flats allow extension of the Mall treatment and a new great memorial on the axis of the Capitol and the Monument and near the river-bank — a memorial to Lincoln, whose is the one name in our national history which the world couples with that of Washington. The gardens to be formed west of the Monument would add impressiveness to the obelisk and bring it into axial relation with the White House, thus simply carrying out L'Enfant's idea of placing the Memorial to Washington upon the axes of the Capitol and the White House. This garden surrounded by terraces with groves of elms becomes the gem of the entire park-system.

South of the Monument extends a space devoted to out-of-door sports, to gymnasiums and playgrounds, swimming and skating pools. And here is a great *rond-point* where a monumental structure with some figure symbolic of the Republic would be proper.

The site of the Lincoln Memorial becomes the point of divergence for driveways leading southwest to the Potomac Park, for the Memorial Bridge leading directly to the mansion at Arlington and to the embankment carrying the driveway to the mouth of Rock Creek whence it continues up the valley of Rock Creek to the Zoölogical Park and Rock Creek Park. The Committee advocates parking the sides of Rock Creek, controlling and policing them, and is opposed to the project of filling-in.

For the section west of Rock Creek the plans contemplate driveways along the Potomac gorge even to Great Falls, and diagonal connections by way of picturesque valleys to the Rock Creek parks.

Park-connections are recommended east of Rock Creek Park to Soldiers' Home by way of Piney Branch, a gorge not less beautiful than the valley of Rock Creek, into which it opens, and also along Savannah Street, widened into a parkway. This latter allows a fine

reciprocity between the proposed Municipal Hospital buildings and the new structure to be erected at the Soldiers' Home.

Connections are also planned between the Home and Anacostia Creek, over wooded hills giving wide views of the city.

The swampy valley of the Anacostia should be transformed into a park for boating, swimming and skating, with encircling drives, walks and pleasure-grounds.

The use of the Thames by pleasure-craft is referred to, and also Belle Isle Park at Detroit, with shallow lakes and canals, upon which thousands disport themselves, boating or skating where was formerly only a marshy island.

This water-park with drives about it is planned for Anacostia above the head of navigation. The treatment of the navigable part, down to its junction with the Potomac, proposed is one of a walled channel and filled-in flats, with also a broad parked driveway by the river to connect Anacostia Park with Potomac Park, and a line of stone quays overlooked by terraces, as along the Seine at Paris.

The long island in the river opposite the Washington channel will be treated so as to provide shaded drives and walks along the water, with frequent boat-landings, in order to make this Potomac Park perfectly accessible to the section of the city it adjoins.

The wharves along the river-front should be rebuilt to be in keeping with the Government improvements at Arsenal Point for the Engineers' School and War College. The rentals for use will pay for this work.

There should be no slips to impede the ebb and flow of tide and force of current, but a continuous line of masonry quays.

Water Street will be broadened for a driveway between Potomac and Anacostia parks.

The models of a portion of the city, from the Library of Congress west to the Potomac, were indispensable aids to the designers, and will be guides for the carrying out of the plans, so that, no matter how long a period the work may cover, no departures from the approved designs need occur.

Numerous detail drawings were made and rendered by capable illustrators.

The plans call for systematic work, continuous over many years.

The parks and reservations are now under control of various officers and boards working duly, but not always in harmony.

For the sake of economy and efficiency a park commission should be created to control the entire park-system of the District of Columbia, national rather than local in character, and to work under the immediate control of the President of the United States.

The Report winds up by stating that it is impossible now to estimate the cost of carrying out these plans, nor is it necessary.

The procedure would be the addition of new public buildings and spaces from time to time, and of the facilities necessary to city life as fast as the need of such is realized, the work to be done within the limits of plans at once comprehensive, simple, adequate and dignified. "In such manner only can there be a development of the District of Columbia worthy of the nation."

So ends the Report of the Senate Committee on the District of Columbia which submits to the Senate the results of the study by the four artists appointed to aid them.

The Report gives the proposals in sum and with its appreciation and approval.

The Commission went abroad during the summer, accompanied by Mr. Charles Moore, Secretary to the Senate Committee on the District of Columbia, who acted as their secretary. They visited Rome, Paris, Berlin, Buda-Pesth and London and some of the smaller European capitals where examples of civic architecture are to be sought. They brought back a mass of photographic data which is now on exhibition with the rest.

The plans, sections, models, views and detail studies which accompany their Report have been arranged by Mr. McKim for exhibition at the Corcoran Art Gallery.

The maps, plans, bird's-eye views, diagrams, sections, etc., are in one room. On the hemicycle floor stand the two large models, the one of the existent Washington, its neighbor the Washington to be. Around the walls hang beautiful drawings rendered in color, of general views from several points and of details of treatment. Above them are enlargements from views in foreign cities,

One looks down upon the models from a platform. They are upon high bases, so that the eye may study them from all points and heights. Their utility is incalculable. There is a separate model, placed elsewhere in the Gallery, giving the treatment about the Washington Monument to a scale of one thirty-second.

The whole is a masterly presentation of the most important work of artistic significance ever projected in the United States. It marks an epoch in our national progress. It educates. It calls aloud for realization. It crowns gloriously the labors of this Commission and should effect their retention as a permanent board to inaugurate the plan they have conceived and to direct what the nation should do in the arts which they so honorably represent before the country.

The largeness of view shown by the Senate Committee in its conduct of this matter is instructive and encouraging.

[To be continued.]

STATUE OF ROCHAMBEAU. — Secretary Root has asked Congress to make an appropriation of $15,000 to provide for a suitable foundation, and to arrange for the unveiling of a replica of the bronze statue of the distinguished Frenchman, Rochambeau, to be erected in Washington. — *Exchange.*

BOOKS AND PAPERS

THE first time we had occasion to turn to Mr. Sturgis's just finished dictionary[1] for desired information we found our expectation denied, and that the term which escaped the notice of the staffs of the editors of the "*Century*" and the "*Standard*" had escaped his too. This is not to say that any dictionary of the three is "wanting," but merely that none contains the term "stilt-block" which, in his new "*History of Architecture in Italy*," Mr. Charles A. Cummings has such frequent occasion to use in his descriptions of the ordonnance of Byzantine and Lombardesque buildings in the north of Italy, and very possibly is a translated equivalent for the German "*Stelzblock*," or some such compound. It is in itself an excellently descriptive word, and seemingly deserves a place in an up-to-date dictionary.

Of course, the real test of the value of a dictionary is the manner, satisfactory or the reverse, in which it affords comprehensive answers to every-day questions, and though Mr. Sturgis has seemingly failed us in this one instance, we do not doubt he will in many a future case cast the rays of his greater intelligence into our unenlightened minds. It is really humiliating, after more than a quarter of a century devoted to reading a greater amount of architectural literature than falls to the share of most practitioners, to find how very limited one's own architectural vocabulary is after all. Fortunately, if one does not undertake to add to the bulk of architectural literature the work of one's own pen, a limited vocabulary is not a vital disqualification in one's life-work. It is questionable whether a Scotch gardener grows any better flowers for knowing their Latinized botanical names, or whether an architect shows less artistic feeling in his design because he is ignorant of the really proper term belonging to each member of his composition.

For real every-day usefulness, it is to be regretted that this work was not arranged on a different scheme, or, rather, that its contents were not differently grouped. There are three volumes, and the contents of each volume are purely miscellaneous in character, with only the alphabetical index on the back to inform the seeker what he is likely to find between the covers of the volume he lifts from the shelves. Now, if we may trust our observation, the contents of these three volumes easily and naturally fall into three distinct groups of approximately equal bulk. First, there is Mr. Smith's excellent biographical work, which seems to occupy at least a third of the entire space, and which, as we have said before, deserved to be presented as a biographical dictionary on its own merits. Next, there is the encyclopædic matter proper — the historical articles, the treatises on architectural styles, etc., and many longer articles, argumentative and theoretical rather than merely descriptive: these, too, seem to consume in bulk about a third of the entire printed matter. Finally, there is the remaining third, the brief descriptions of terms, phrases and processes properly to be sought in a dictionary. We feel that if the matter had been divided and grouped on this principle the owner would have found that he had three very useful volumes on his shelves, and that he could turn to one or another of them with the confident knowledge that he would not have to waste time in turning over countless pages that did not interest him before he came to the single tiny fact he was in need of. Well, the work cannot be undone, of course, but an opportunity has been wasted, and the really useful architectural dictionary, pure and simple, is still to make.

One of the excellent devices employed is the appending to a given article of a more or less complete bibliography which cites either the authorities which have actually been consulted in the preparation of the article in question, or to which the reader may turn for fuller and further illumination. But, excellent as this device is, it does not quite take the place of a bibliography indexed under subject-matter, and the very good bibliography indexed under the author's name which closes the third volume is very far from being a satisfactory substitute. Thus, if one happens to want to read up on public baths and wash-houses, he finds no bibliographic clues either under "bath" or "wash-house," and, unless chance directs his eye to "Allsop, R. Owen," in the author's index, he will be justified in feeling that Mr. Sturgis's industry has failed to provide for his legitimate needs. Prefixing this bibliography, which occupies the closing pages of the work, we find a note which declares that, of the books enumerated below, "those from which illustrations have been drawn are indicated by an asterisk," and we find that, in this graceful way, acknowledgment is made to the authors and publishers of some seventy-five or eighty architectural works of such high character that their illustrations seem to have been selected as fit above all others to illuminate this work. As a glittering generality, a general acknowledgment in the form of an asterisk may be accepted as properly symbolic, while its lack of effusive cordiality certainly does suggest the chill of stellar space. It seems as if here we stumbled upon most unfortunate evidence of ethical obtuseness on the part of a responsible some one. The manner in which the illustrations have been procured and the careless way in which

[1] "*A Dictionary of Architecture and Building*," Biographical, Historical and Descriptive. By Russell Sturgis, A. M.; Ph. D.; F. A. I. A., and many Architects, Painters, Engineers and other expert Writers, American and Foreign. In three volumes. Vol. III, O-Z. New York: The Macmillan Co. 1901. Price per set, cloth, $18; half-morocco, $30.

the proprieties of scale have been disregarded we spoke of when the first volume appeared, but it speaks volumes for the real intelligibility of the common language that architects of every nationality use, that illustrations drawn from seventy odd different books, the work, possibly, of thrice that number of different draughtsmen, can be brought together in a single publication, and not produce more unpleasant jarring of the optic nerve. There is this to be said of the method adopted by the publishers in illustrating Mr. Sturgis's work: If they had gone to the expense of preparing proper original illustrations, approximately equivalent in merit and accuracy to those actually used, it would have been necessary for them to charge at least twenty dollars per volume, in place of six dollars, and it is probably because of the manner in which the illustrations have been "conveyed" from so many different sources that the publishers have been able to fix the price for this really valuable work at a limit which brings it within the reasonable reach of every one.

The third volume, which has about the same bulk as each of its predecessors, has much more the air of a dictionary than they, particularly the second volume, had. There seem to be a greater number of entries and fewer long encyclopædic articles, more brief definitions and fewer mere dissertations. In short, it looks like a dictionary, and so invites use, and makes us all the more regret that the definitions were not segregated in a single volume. It is not at all impossible that the editor found it needful to do more pruning on the matter prepared for this volume, if it were to be compressed into the limits fixed by the publishers, than seemed necessary or desirable in the earlier volumes. This is a fate that is common to all such undertakings. Planat's remarkably valuable "*Encyclopédie de l'Architecture et de la Construction*" proceeded in a most acceptable and satisfying manner through five volumes, the treatment in one being identical with that in the others, and then the publishers seem to have noticed for the first time that the editor had reached only the letter N. Then the screws seem to have been applied, and the remainder of the alphabet was disposed of in a single volume in a much less satisfactory manner. Mr. Sturgis has known how to plan his work better than this, and his final volume does not exhibit the enforced omissions and undesirable suppressions which M. Planat had to endure. Whatever condensation this third volume had to undergo has been distinctly to its advantage.

The volume is not altogether devoid of encyclopædic articles; they are only shorter. Mr. W. P. P. Longfellow rounds out the subjects treated by him in the second volume with papers on "Romanesque Architecture" and the "Round Church," while Mr. R. Phené Spiers writes of "Roman Architecture" and, again, of "Syria," topics both of which his extended travels admirably fit him to deal with. When Mr. C. H. Blackall held the first Rotch Travelling Scholarship he was particularly interested in the architecture of the Iberian Peninsula, and it was natural he should select "Spain" and "Portugal" as the subjects he would contribute to this *magnum opus*. Professor Frothingham supplements his interesting article on "Italy" in the second volume with a similar article on "Sicily" in this one, and Professor Hamlin deals with architecture as widely variant as is implied by the headings of his two contributions, "Persia" and "Scotland." Montgomery Schuyler writes the article for "United States," devoted largely to the earlier architectural developments, since so much that is modern has been treated under other headings, as "Office Building," "Synagogue," "Church," "Hotel," "Theatre," and so on. Mr. Sturgis himself treats the architecture of sundry other countries, seemingly those which he could find no one else particularly desirous of handling. But in no case have these historic articles the expansion and comprehensiveness of the similar articles in the second volume.

Among the longer articles, not primarily historic in character, may be cited Mr. E. M. Wheelright's paper on "Schoolhouses" and Mr. George P. Merrill's on "Stone," contributions both of which may be accepted as coming from competent authorities, and so, too, may Mr. La Farge's paper on stained-glass under the general heading "Window."

Some things in the volume strike us as a little singular. No one writes more delightfully or suggestively than Mr. Henry Rutgers Marshall, but the points he makes and the views he advances are so personal to himself that the reader feels himself invited to an immediate discussion with him of the point at issue. Now, one can sit down to discuss, even to answer, an essay in pamphlet form, but who would ever think of answering an article in an encyclopædia? and his essay introduced under the heading "Preliminary Studies" is just one of those things that afford many chances for discussion and controversy, and so, being largely debatable, are a little out of place in a dictionary. For instance, we do not feel at all sure that it is "self-evident that a building which is beautiful only to the technically trained architectural translator, and not to the average highly cultivated man, is not a work of architectural art at all."

In a different way, while we may be very glad to know what Mr. George L. Heins has to say, we think that no one would ever search for it under the heading "Refinements in Design," and we feel quite sure, further, that no such heading, quite regardless of the matter to be found under it, is ever likely to be sought under the letter R.

Another editorial vagary seems to be the placing of Mr. Walter Cook's interesting account of the Prix de Rome not under that title, but under the heading "School of Architecture."

It may seem unreasonable to complain because a dictionary has no index, but this work is in crying need of an index to its illustrations, and all the more because of the singular way in which the editor has chosen to title his plates, the specific title of the subject being quite lost to sight, being seemingly grudgingly mentioned at all.

Some four or five years ago we wrote with warm approbation of the "*History of Architecture*,"[1] prepared as a text-book for the schools by Professor Banister Fletcher and his son, and the frequent use we have made of the book in the intervening time has proved that we did not mistake its useful character. There are not many architectural books which a publisher finds there is profit in reprinting, but this one of the Messrs. Fletchers' ran through three editions — of unstated size be it said. It is fair to grant that but for its adoption as a text-book by colleges and schools of art and by University Extension lecturers, it would probably not have had an unusual sale, but its very adoption by these institutions is proof of its worth. The second and third editions were reprints of the original.

Finding the work was "a seller," the younger man, after the death of his father, resolved to revise and amplify the divisions of the original work while adding a considerable chapter, or division, on the non-historic styles — Indian, Chinese, Japanese and Saracenic. Fortunately, he found his publisher, Mr. B. T. Batsford, ready to meet him more than half way, and the result of their combined efforts is one of the most notable new editions that we can recall. The book, which was originally a small octavo, now appears as a medium octavo containing some two hundred more pages than were in the original, and exhibits a larger and fairer page of print than did the first edition, although that exhibited a more agreeable face than do most books of the kind.

Although very considerable additions have been made to the text-matter, the enlarged size of the book is due mainly to the increase in the number of the illustrations, which now occupy 256 plates, one half of which are half-tone prints from photographs, while the other half exhibit in compact form 1,300 illustrations so skilfully arranged that each plate, in place of being a mere hodge-podge of dissociated and mutually interfering forms, has generally a most attractive air. In some cases the grouping and balance of the cuts on the plate could not be improved, and the draughtsman, whoever he is — and he deserves to be known — has evidently given so much thought to securing a properly balanced effect, and has so generally succeeded, that it may be taken for granted that in those cases where he has failed could no one else have succeeded better. The manner in which these line-drawings have been prepared is wholly admirable, and the only ground we have for complaint is that the necessary descriptive titles and remarks are lettered on the drawing in open lettering, and, as a rule, fill up all available blank spaces. The result is that some pages have a bewilderingly dizzy aspect, and the student cannot at once determine which is the illustration and which the explanatory text. It is rather regrettable that the printer, who has done his part of the work with such typographical excellence, was not allowed to title these prints. But the really remarkable thing about these plates is that the illustrations in the first edition have not been simply reproduced at the larger scale of the new edition — they have been redrawn, and very materially improved in the process. That word "process" reminds us how greatly the art of making half-tone process-plates has improved in the last few years: the process-plates in this edition are, as a rule, far more satisfactory than the collotypes used in the first edition.

We must also point out one further particular in which author and publisher have used their intelligence for the public good. They are ready to furnish these illustrations to schools and lecturers either in the shape of lantern-slides or lecture-diagrams, 27″ x 40″ in size.

Comparisons are uncomfortable things to institute, but we really wish the publishers of Mr. Sturgis's "*Dictionary of Architecture*" would get a copy of this book, for we believe it would be an object-lesson, and that they could learn from it that there is a proper as well as an improper way of providing architectural illustrations.

With all that we have said in favor of the illustrated portions of Mr. Fletcher's work, we must complain that some one has again displayed rank stupidity in not providing an index of illustrations. We have a "list of illustrations" arranged in the ordinary silly form of a list printed in the order in which the cuts happen to be paged in the book, but there is no possible way of putting one's finger on a desired illustration save by hunting at random for it. This is all the more irritating because the "list of illustrations" is in itself admirably arranged in certain particulars, and it only needed a slight exertion of common-sense to throw the present meaningless arrangement into a sensible and self-revealing alphabetical sequence.

The character of the work itself can be noted from the following extract embodying a comparative statement of the characteristics of French and English Gothic: —

4. COMPARATIVE.

Amiens Cathedral (No 120) is the most characteristic French cathedral, in the same way as Salisbury (No. 120) is considered to be the most typical English cathedral.

---

[1] "*A History of Architecture on the Comparative Method*" for the Student, Craftsman and Amateur. By Prof. Banister Fletcher, F. R. I. B A., and Banister F. Fletcher, A. R. I. B. A. Fourth edition, revised and enlarged, with 256 plates, comprising 1,300 illustrations. London: B. T. Batsford. Imported by Charles Scribner's Sons, New York. 1901. Price, $7.50.

FRENCH GOTHIC.

(*a*) *Plans* (No. 120). — Short, wide and high. Length about four times the width.

In the south richly designed cloisters are frequently met with, otherwise they are rarely found.

Transepts have slight projection, as may be seen in the sheet of comparative plans (No. 116).

Large number of side chapels, due to the popular character of the Cathedral as compared with the Abbey.

The circular apse is developed into *chevet*.

Läon, Dol and Poitiers are notable exceptions.

There are sometimes double aisles, as at Notre Dame, Paris (No. 118), Le Mans (choir), Bourges, etc.

Two western towers (Nos. 115, 122 and 123) characteristic, the probable reason being that the great height of nave prevented a central tower to be constructed

Compare central *flèche* at Amiens (422 feet high) (No. 126 B).

In Normandy, central spires are common.

The French attempted to combine many towers, placing four at the internal angles of the transepts, and two at the west end, with central *flèche* only, as at Läon, Amiens (Nos. 115 A and 126 B), etc.

Wide spacing of arcading and general largeness of parts. No polygonal chapter-houses.

(*b*) *Walls.* — Early buttresses developed from the slight projections of the Romanesque period. They are sometimes semicircular columns attached to the walls, especially in the apses of churches. Later buttresses have chapels between them (No. 118).

Flying-buttresses are common, and are used with special effect at the east end. They are largely employed, being necessary on account of height and width of aisles and naves.

Offsets to buttresses are flatter as they are higher. Buttresses often nearly vertical, without offsets (No. 114).

Interiors owe their effect largely to their extreme height, otherwise they are considerably less ornate than the English examples.

Open tracery parapets occur (Nos. 125 and 126 C, D).

Characteristic west front is Notre Dame, Paris (No. 117).

(*c*) *Openings.* — Doorways elaborate and rich, larger and finer than the English, and deeply set in west fronts, as at Coutances and Notre Dame, Paris (Nos. 117, 122 and 123).

Windows have much "plate" tracery, "flamboyant" tracery final development.

Notice the absence of cusps in late French tracery.

Large circular windows in west fronts (Nos. 117 and 121), and transept ends (No. 114 B), with intricate tracery, are a special feature.

(*d*) *Roofs.* — Roofs always steep and ornamented (Nos. 115 and 125).

Slates often employed. Construction with double timbers of special type to surmount high vaults.

Early development of the vault, which is specially characteristic of the style. A striking feature of the "flamboyant" or later period is the frequent use of pendants in vaulted roofs.

ENGLISH GOTHIC.

(*a*) *Plans* (No. 120). — Long, narrow and low. Length about six times the width

Cloisters frequent, owing to monastic foundation, and characteristic of English cathedrals.

Transepts have bold projection, and a second eastern transept is found, as at Salisbury, Lincoln, etc.

Small number of side chapels, due to the fact that the principal cathedrals were churches belonging to monastic foundations.

The square east end characteristic. The "Nine Altars" at Durham as an east end transept is remarkable.

Practically always single aisles; Chichester is the only example to the contrary (see page 216).

The central tower the most successful and predominant feature, as Lincoln (Nos. 88 B and 94), Canterbury, Durham, York, Ely and Gloucester (No. 88).

A single western tower is characteristic of parish churches.

The English were content to group three spires, placed on a central and two western towers, as at Salisbury (Nos. 88 A and 90), Chichester (No. 86 A), and Lichfield (No. 88 F.)

Close spacing of arcading and smallness of parts in main features. Polygonal chapter-houses typical.

(*b*) *Walls.* — Early buttresses are flat projections. Later ones are much pronounced, and strongly marked with offsets and pinnacles.

Transitional buttresses may be seen at Salisbury with curious weathering.

Flying-buttresses, although occurring in many examples, are not so prominent a feature because the clerestory is kept comparatively low.

In the absence of the *chevet*, these features are somewhat unimportant in the general effect.

Offsets to buttresses are steeper as they get higher. In the later periods, highly ornamented with niches and panelling.

Interiors are ornate, owing to elaboration of the triforium, complex pier arch mouldings, variety of clerestory treatment and richness of the vaulting.

The battlemented parapet predominates (No. 111 M).

Characteristic west front is Peterborough (No. 87 C).

(*c*) *Openings.* — Doorways more simply treated and placed in less important position on south front, and often provided with a separate porch, elaborate and characteristic — Salisbury, Canterbury, Lincoln (No. 94), etc.

Windows develop on the same lines, but "plate" tracery seldom used, "perpendicular" tracery final development, and especially characteristic of English work.

Circular windows are not much used in England, but are found at Westminster and Durham.

(*d*) *Roofs* of moderate pitch, approaching to flatness in later periods.

Lead coverings generally employed. Carpentry is more advanced. Single framed timbers are used

Ornamental wooden roofs were more highly developed than in France (No. 85). Fan-tracery vaulting (Nos. 84 and 99) peculiar to England.

FRENCH GOTHIC.

French vaults are usually domical, and ridge ribs are rarely employed. Very slight development in vaulting takes place. Intermediate and lierne ribs seldom used. Compare Gothic vaulting (page 188), (Nos. 81 and 84).

Extreme height, as at Amiens, which is 140 feet (No. 121).

The joints of the web (or infilling) are at right angles to the wall ribs (No. 119).

(*e*) *Columns.* — Plain circular nave columns are characteristic, as in Notre Dame, Paris (No. 126 H).

The use of columns seems due to Roman tradition; the capitals have foliage of the Corinthian type. There was a difficulty in bringing down the lines of the vaultings with this type, and we find clumsy expedients in use, as when the shafts started just above the square abacus of the arcade columns (No. 119). In the south is found the square pier with attached half-columns (No. 126, J, K, L).

(*f*) *Mouldings.* — Less bold and rich. Often kept some distance from window-openings.

Early application of stiff leaf foliage to capitals, classic type of foliage lasting well into the period (No. 126).

The square abacus is a great French feature (No. 126 G, H). The moulded "bell" capitals without foliage rarely met with, except in Normandy. The Crocket capital (No. 126 P, Q) a characteristic feature.

French work being on a larger scale, features are rougher, and less attention is paid to detail.

(*g*) *Ornament.* — Decorative figure sculpture best exemplified at Chartres (No. 126 A), and Notre Dame, Paris. Carving of animals and birds also much used (No. 126 G.

In early stained-glass there was a fine development, Chartres possessing so many examples as to give an idea of the general effect of an interior, when completed, according to the intent of the artists of the epoch. Depth and strength, in a prevailing tone of blue tending to violet, is the impression produced. Color work seems to have fully developed, and it would appear that hangings were imitated in painted wall-decorations.

ENGLISH GOTHIC.

English vaults have level ridges and have ridge ribs in both directions. A heavier section is employed, and this backbone, given to the vaulting by such ridges, may be traced to the influence of carpentry (No. 83).

The joints of the web are often parallel to the wall rib or at right angles to a dividing line, starting from the angle of the compartment to the centre of diagonal.

(*e*) *Columns.* — The clustered shaft is a special feature (No. 112).

The early adoption of shafts as expressive of the vault lines and the composition of them, being taken as the basis of the pier, avoids any such difficulty (No. 92).

In France, however, the mouldings of the pier arches often die into the pillars without capitals, as at St. Lo. In England the development of moulded piers was a final feature.

(*f*) *Mouldings.* — A special striving for the development of mouldings in capitals and arches.

The moulded bell capital obtains in England (No. 112), but early carved caps are notable (No. 113), having stiff-leaved foliage.

The English abacus is round or octagonal as a rule (No. 113).

The "dog-tooth" ornament (No. 111 A) so common in the Early English period of Gothic architecture does not occur in French work.

The small scale of English work led to greater refinement and attention to detail.

(*g*) *Ornament.* — English decorative sculpture is best seen at Wells, Lichfield and Westminster, the west front of the former being perhaps the most complete in England.

The few early windows of Canterbury (see under E. English) remain as a proof of the capabilities of the style. The development of painted glass is explained under each section in the chapter on English Gothic.

Color appears to have been applied to sculpture. In the early period it probably followed on French examples. The colored roofs of the perpendicular period are notable.

THE HERMES RECOVERED NEAR ANTICYTHERA.

LAST March, through the kindness of Professor Richardson of the American School at Athens in sending me two Athenian papers, I was privileged to give the readers of the *Transcript* a detailed account of the remarkable find of statues at the bottom of the sea near the island of Anticythera, off Cape Malea. The best of these was a splendid bronze statue, preserved practically entire though in fragments, and now generally called a Hermes.

The recovery of the shipload of works of art so strangely preserved for us by the sea-god has been going on since that time, though a report early this fall stated that operations were hindered by a rock which was too large to be removed by the means at hand, but was to be blown up with dynamite.

Meanwhile, the fragments at Athens have been cleaned, and the Hermes partly restored, though but temporarily, for few men have the skill and experience requisite to the task of successfully fitting together a large number of pieces of bronze. Various propositions have been made to and by the Greek Government. One of these, strangely enough, came from Turkey. Through Mr. Mavrokordatos, the Greek Minister at Constantinople, Moustapha Bey, the best sculptor connected with the Imperial Museum in that city, expressed his desire to be allowed to undertake the piecing together of the Hermes. The Greek Ministry at Athens, before accepting the proposition, directed Mr. Mavrokordatos to seek further information about this sculptor. The Government also wrote, through Mr. Kabbadias, Ephor-General of Antiquities, to a sculptor at the Louvre, asking him to come to Athens and undertake the work. The result of this overture I have not seen reported, but, at the request of the Greek

Government, Herr Wilhelm Sturm, the restorer of the archæological collections of the Imperial Palace at Vienna, was permitted to come to Athens in October to give his expert opinion on the restoration of the statue.

A friend at Athens has sent me a clipping from the *Asty* containing his official report to the Minister of Ecclesiastical Affairs and Public Education, Mr. Staes, in whose department is included the care of antiquities.

After a formal introduction, he states, as a result of careful examination, that the bronze fragments of the statue are sufficiently strong and thick to endure the process of fitting together. Moreover, the missing portions of the trunk are so few and so unimportant that no difficulty will be presented in restoring the statue to its original form.

He has much praise for the work already done on the Hermes, saying: "I ought not to omit to mention with commendation that this most happy result, which will enrich the collections of the National Museum by a masterpiece of bronze sculpture, is due in the first place to the exceptional foresight and care with which the cleaning and preservation of the fragments, and, in general, of all the bronze finds, were carried out in good season by your Ministry. I am glad to be able to express my opinion that the method employed, which was the only one that could check the progress of dissolution which had begun, is shown to be wholly equal to the possibilities of the art to-day, and the future restorer has nothing more in this respect left him to do."

Herr Sturm then goes on to describe the method of restoration as follows: "In fitting together the statue the experience will be useful which was gained in the case of the large bronze statue of an athlete from Ephesus which is now in the collections of the Imperial Palace in Vienna. The method is this: the fragments are bound together on their inner surface by strips of brass and screws of the same metal, and in such a way that the latter do not project at all on the outer surface, but rather are rendered entirely invisible by the coating of patina. When the preserved fragments have been thus bound together, the hollow form of the body thus formed is fitted by brass pins upon a skeleton of tinned iron extending through the trunk, arms and legs.

"However, since we must provide against changes resulting from the chemical action between the metallic parts thus bound together, even when the statue is unmoved, not to speak of earthquakes, and also against the appearance of new breaks, it is quite necessary that the hollow within the statue should be filled with a solid core.

"As I regard metal unsuitable for this, I make use of a cement invented by myself, which, besides the relatively small weight, presents also the advantage that as soon as it hardens, because it absorbs no moisture, it becomes absolutely solid. Where this projects on the surface because parts of the statue are missing, it is easily fashioned, and by a special process and coloring is made like the metal in texture and shade.

"For setting up the whole there will be considered a bronze base, in which, without technical difficulties, a hollow can be made corresponding to the leaded projection at the lower extremity of the leg, on which the statue stands."

Herr Sturm expresses his earnest desire to perform himself the task of restoring the Hermes, but the work would require six months' time, and two more must be added which the core of cement needs to dry completely. His duties at Vienna are such that he does not expect permission for a longer absence, and so cannot undertake the work if it must be done at Athens. If, however, the restoration can be made at Vienna, he already has permission to give his time and attention to it there. The objections to the removal of the precious find to the Austrian capital he thinks of no weight compared to the advantages of this plan. The transfer of the fragments can be made without the least danger, for there is hope that through the influence of the royal Government permission will be given by the railroad and steamship companies to those in charge of the statue to manage themselves all necessary transfers, and to keep the boxes under their surveillance all the time, travelling in a private compartment. In Vienna the precious statue will be deposited in the private rooms of the Imperial Archæological Museum immediately on arrival, will be accessible to no unauthorized person, and will have the same protection as is furnished to the treasures of the Imperial Palace, and of this both the Greek representatives and especially His Excellency Mr. Manos, the Greek Ambassador at the Imperial Court, may be assured.

Another reason why it is better that the work should be carried on in Vienna is that in the workrooms of the Court Museum are all the appliances, some very expensive, which were tested in the work on the bronze statue from Ephesus. And perfect and approved tools are so much the more necessary as he would feel obliged to prepare everything required for the work, even to the last screw, with his own hand. The loan of the tools of the imperial workrooms is absolutely forbidden, and it will be difficult to have perfect ones made at Athens. So on this account he urges most strongly the transfer of the Hermes to Vienna.

The proposal that the work be done at Athens by local artists under his oversight he deems unwise, for though he would gladly give his services, and even supposing permission for his absence from Vienna were granted, he would be hardly more than an adviser, and could not do the work with his own hand. The Athenian workmen lack his experience, and the statue might be sadly injured by experiments on their part, while the metal might be weakened by boring new screw-holes to rectify mistakes he might discover.

Notwithstanding Herr Sturm's arguments, the Greek Government is still naturally reluctant to allow the Hermes to leave the country, and has made an effort to secure this expert's personal services in its restoration at Athens, requesting the Austrian Government to permit his absence for the necessary time. This effort seems to have been successful, for the New York *Atlantis* of Nov. 1 contains the following item: —

"The Directors of the Austrian Archæological Institute have announced by telegram to Mr. Kabbadias, the Ephor-General of Antiquities, that permission has been given to Herr Sturm to come to Greece to put together the statue of Hermes, the expenses of his journey being assumed by the Austrian Institute in grateful acknowledgment of the help which the Greek Government furnishes its representatives in Athens."

The last number of the *Jahrbuch des Kais. Deut. Inst.* (*Archäologischer Anzeiger*, page 148), under the date of Oct. 17, gives a good picture of the bronze statue of the athlete from Ephesus mentioned above. This is of life-size, representing an athlete anointing himself, and was put together from more than two hundred fragments. It stands, with other pieces from Ephesus, in the so-called "Theseustempel" in the Volksgarten at Vienna, where Canova's group of Theseus and a Centaur formerly stood.

In the last issue of the *American Journal of Archæology* (Vol. v., No. 3, page 339) is a list of the articles on these finds off Anticythera. — *Arthur Stoddard Cooley in the Boston Transcript.*

WASHINGTON CHAPTER OF THE A. I. A.

WASHINGTON, D. C., January 27, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sir, — The enclosed printed matter was endorsed by the Washington Chapter of the American Institute of Architects at a meeting held January 25, 1902.

I have been asked to forward you the same and request its publication. Yours very truly, F. B. PYLE, *Secretary.*

We, ——— ———, a Society interested in the development of architecture and art in the United States, understanding that legislation is proposed changing the title of Architect of the U. S. Capitol, apparently upon the theory that the services of a trained architect are not required, and that the services which might be rendered to the country and Congress by a trained architect are not needed in this official, respectfully request careful consideration of the following preambles and resolution before any action is taken in the matter: —

Whereas, The title of Architect of the U. S. Capitol is an honorable and historic title which has been in existence one hundred and ten years, the position has only been held by such honored architects as William Thornton, B. H. Latrobe, Charles Bulfinch, Robert Mills, T. U. Walter, and Edward Clark; and

Whereas, The various incumbents have been of great service to the Government of the United States in the growth of the building on artistic and harmonious lines, and of great service to Congress as consulting-architect on various buildings, monuments, statuary, and matters of construction which have come before Congress for consideration for over a century; and

Whereas, At the beginning of the twentieth century the contemplated artistic development of Washington, submitted by the Park Commission, will make it more important that the building should continue to be developed in harmony with the present structure and in keeping with the best artistic and architectural practice of the country, and Congress will have greater need for a trained consulting-architect with the contemplated improvements of Washington before them for consideration and development; and

Whereas, The constant increase in the architectural knowledge among the people of the United States demands that the building in which, more than any other, all take a natural pride shall be developed in accordance with the highest standard of architectural art; and

Whereas, It is the rule among the most enlightened nations of the world unfailingly to place an architect of high attainments in charge of all monumental buildings; and

Whereas, The officer in charge will be almost daily called on for advice relating to design, construction, decoration, and sanitation, and only a trained architect will be able to give advice that will be of the best service to Congress and the country at large; and

Whereas, It is possible that even now work is in progress that may prove detrimental to the dignity and refinement of the building, and may ultimately have to be removed to make it in keeping with the building and good architectural practice: Therefore, be it

Resolved, That our Association, in the interest of the Capitol building and its continued development on harmonious and artistic lines and proper methods of construction, earnestly ask that the title be not changed; that the work in progress on the building be examined by competent experts who shall report to Congress, and that the President appoint an architect at as early a date as possible.

ANTIQUITY OF CUNEIFORM INSCRIPTIONS. — The archæological discoveries of M. de Morgan at Susa are throwing much light on prehistoric civilization. In the Anzanian capital, destroyed in B. C. 640, M. de Morgan found many inscriptions which proved that writing in the cuneiform character was introduced from Babylonia probably about B. C. 3800, when Elam was conquered and annexed by the Semitic rulers of Chaldea. — *N. Y. Evening Post.*

A COMPETITIVE DESIGN FOR THE ROSWELL P. FLOWER MEMORIAL LIBRARY. MESSRS. BRUN, HAUSER & LAPOINTE, ARCHITECTS, NEW YORK, N. Y.

PUBLIC LIBRARY, THOMPSON, CONN. MESSRS. GAY & PROCTOR, ARCHITECTS, BOSTON, MASS.

THE library building at Thompson is in gray stone, Spanish red tile roof, quartered-oak finish and floors, plate-glass windows; interior richly decorated in color; books on steel stacks; steam heat, open plumbing. There are reading, periodical and book rooms, librarian's room, toilet, etc., lift, basement to attic; storage, and opening on ground-floor into book-room; main entrance-hall, high-domed ceiling. All rooms high and with coved ceilings. Fireplace in reading-room. Cost, $18,000.

NOTES AND CLIPPINGS

MUDDY WATER AND AUTOMATIC SPRINKLERS. — Muddy river-water and sprinklers are incompatibilities, as was seen the other day when the soap-works and refinery of the Union Oil plant at Gretna, opposite New Orleans, took fire. The resultant damage was serious. The risk was equipped with sprinklers. It was, therefore, a surprise all round that the loss should have been so heavy. An investigation proved, however, that the sprinklers had been rendered useless by a deposit of mud. The heads were pendant, and, therefore, collected mud more readily than upright heads would have done. Many of them were so stopped up as not to operate, and all of them were, no doubt, so delayed in operating as to cause the disaster which has so disappointed the underwriters. The Mississippi river-water bears so much silt that pendant heads after having been in use a few years are practically valueless. — *Fire and Water*.

INTERESTING ELECTRICAL-DAMAGE SUIT IN IOWA. — A customer of Swift & Co., the meat-packers of Chicago, was recently killed by the electric current while in one of the firm's cars at Cedar Rapids, Ia., and a suit for $15,000 damages was begun by his widow against Swift & Co. and the Cedar Rapids Electric Light and Power Company. The case against Swift & Co. was brought to trial first, and the jury awarded damages in $2 000. As the verdict was undoubtedly a compromise, the case will be appealed by the defendant company. The testimony showed that Swift & Co. deliver every morning in Cedar Rapids a refrigerator-car of beef, which is run on a side-track near their office. Here the local retail-dealers come to select their meat. The Cedar Rapids Lighting Company furnishes light all over the city, using a 1,000-volt alternating current, which is reduced to 100 volts in the usual manner. The office of Swift & Co. was lighted from a transformer supplying electric-light to a number of customers. There was also a circuit run from Swift's office to an upright near the track, to which, by means of socket and plug, a flexible-cord connection could be made and light carried into the car. The lamps used, in order to prevent breakage, were provided with wire guards. On June 10 last, there was a heavy thunderstorm early in the morning, and a number of persons were shocked, more or less severely, by touching exposed metal parts of circuits when they were standing on the ground or in damp basements. At about 8 A. M. on that day, Mr. Martinek, a customer of Swift & Co., entered the car as usual to select his meat. He held the lamp in his right hand, and when passing it to his left hand, received a severe electrical shock, which resulted in his death a few minutes later. The suit was begun by his widow, the claim being made that his death was due to the fact that the wires of the secondaries at Swift & Co.'s premises had been grounded. Experts from Chicago testified that the grounding was not only permitted by the underwriters, but would be an absolute safeguard as to protection of human life against the high potential current. They declared that the cause of death was due to Martinek's stepping on the king-bolt in the car in his wet boots, which established a connection between the main wire and the ground, sending the high-voltage current through his body. It was shown by witnesses that there was a leak in the transformer, caused by a crack in its cover, through which the water had leaked, and that there must have been a leak on the other side of the primary, which sent the deadly current along the wire. The Company's experts testified that the electric company alone should be liable, and have made this statement to the *Western Electrician*: "It is to be hoped, in the interest of life and limb of consumers of electric-light, that an appeal will be taken, as otherwise a very bad precedent would be established. It goes without saying that the electric-light company should be made absolutely responsible to guard against the entering of the high potential into the secondaries, and should provide safeguards, so that if such an entrance should occur, the dangerous potential should at once be relieved. The latest underwriters' rules recognize these facts, and permit the grounding of the secondaries by permanently grounding the centre of the secondary coil in the transformer; but, of course, it is easily understood that the grounding of any other point of the secondaries, intentionally or accidentally, would be an absolute safeguard to human life against the high-tension current. If the verdict as given should stand, it would simply mean that if a citizen invites a friend into his house and he should by accidental contact with a socket get a fatal shock, under circumstances similar to the ones explained, the host and not the electric-light company would be responsible for his death, if it could be shown that the wiring of the building in which the accident occurred should have been a little defective in some minor points. The absurdity of such a proposition is, of course, apparent to every electrical man, and it is to be hoped, in the interest of the protection of human life, that the Supreme Court of Iowa will reverse the verdict." — *N. Y. Evening Post*.

A SUCCESSFUL WAVE-MOTOR. — The *Scientific American* says that the "city of Santa Cruz, Cal., owns what is perhaps the only practical and efficient wave-motor in existence to-day, and it has stood the test of four years' operation. At a point unprotected by outlying rocks or shoals," it continues, "two wells 8 and 5 feet in diameter, respectively, were sunk in the cliff, one behind the other, the foremost but 5 feet from the brink. These wells extended from 30 feet above high tide to below the ebb and opened at bottom in the ocean. The simplicity of the motor precludes a lengthy description. A counterbalanced float rises and falls between vertical guides in the foremost well as the swells outside raise or lower the water-level. The plunger of a common force-pump working in any part of a long pump-barrel occupies the second well, forcing on the down stroke the salt water vertically 125 feet to a 5,000-gallon tank raised on a 60-foot derrick on the bank above, from whence it runs to tanks along the country roads for miles around and is used for sprinkling purposes. In ordinary weather the pump fills the supply-tank in about one hour. The surplus will also shortly be utilized in the manufacture of salt. But to return to the motor, however. A 35-foot, 4-post derrick carries the vertical guides for pump and float, which are fastened at and near the outer end of a 12-inch round timber 60 feet in length, the butt counterbalanced on the bank over two small iron car-wheels rolling on a short track, and thus allowing the timber to recede and advance as well as to oscillate as its outer end follows the vertical guides. The stopping and starting contrivance, however, caps the climax for simplicity. A strong chain leads from the outer end of the beam above the float over two sheaves at the top of the derrick, and suspends a large barrel in vertical guides at the side. To stop the motor the barrel is filled with water from a short garden-hose attached to a convenient connection from the tank. The weight of the filling barrel gradually overbalances the float, raising it above the waves. When the motor is to start a plug is pulled from the bottom of the barrel and the float gradually goes into action."

EXCAVATIONS NEAR CAIRO. — Robert Sewall is to leave England in a few days for Egypt, where, under the guidance of his friend, Professor Flinders Petrie, he will undertake, near Cairo, a series of excavations. Certain outside reasons exist for believing that a Buddhist mission went from India to Egypt about 250 B. C. No trace has been there manifest; but Mr. Sewall, whose archæological discoveries in India are well known, is to set about digging not very far from Cairo, with a fairly confident heart. He is wished all good luck in his adventure by a large circle of friends, who include his uncle, the venerable Warden of New College, Oxford. — *London Chronicle*.

THE GROWTH OF THE PRACTICE OF CREMATION. — Statistics show that there are now twenty-six crematories in the United States and one in Canada, and that while the number of incinerations in 1884 was only 16, that in 1900 was 2,414. Prior to the year first mentioned and beginning with 1876 there were only 25. — *N. Y. Tribune*.

NOTES AND CLIPPINGS. 48

THE United States Steel Corporation, which, like all the Morgan properties, reports its business clearly and fully to its stockholders, makes a very interesting statement of its recent operations. Its policy, as was promised at the beginning, has been, instead of forcing up prices, to hold them at a reasonable level, with the idea that consumption would be more encouraged by the prospect of stability in prices than by arbitrary fluctuations, even in the direction of reduced cost; and it is said that offers of more than the established prices, for quick delivery, have been refused, the Corporation preferring to treat all its customers alike, both as to delivery and price. This fair and honorable way of doing business has had its natural result, in a steady and large demand, which bids fair to continue. That prices are high there is no question, for, in the seaport cities, foreign structural steel is beginning to be imported in considerable quantities, in competition with the home product, although it has to pay a duty of more than a hundred per cent, besides the cost of transportation, interest and insurance. In fact, as Pittsburgh steel has been extensively sold in Europe in competition with that from the English and German mills, it is not at all impossible that some of the beams imported into Boston and New York may have been made in Pittsburgh, carried four thousand miles to London or Hamburg, brought four thousand miles back again, and sold here, including cost of transportation both ways, interest, insurance and charges, and about one hundred and forty per cent duty, for less than the same would cost sent directly from Pittsburgh. It is true that the difficulty of getting prompt delivery of iron from Pittsburgh, and the prevailing low rates of ocean freight, have probably something to do with the renewal of importations; but one can hardly avoid the reflection that the reduction of the duty on manufactured iron, which Mr. Babcock and his friends are trying to bring about, would mean an immediate shrinkage, to a corresponding extent, in the profits of the United States Steel Corporation.

IT is not impossible that the troubles which incapable sub-contractors inflict upon architects and owners, as well as upon principal contractors, may have had a considerable part in throwing the most important and profitable contracts in city work into the hands of great constructing firms or corporations, which offer to contract for a building of any size, complete and ready for occupancy, staking their reputation and their capital on the sufficiency of every branch of the work. It is currently reported in the building world that some, at least, of these corporations make enormous profits, at the same time that they give reasonable satisfaction to the owners and architects of the buildings which they carry out; and the reason of their success is to be found, in the opinion of most experts, in the control which they exercise over their subordinate contractors, who work, as a rule, only for them, and are, consequently, ready to do what they are called upon to do at the time, and in the manner, required of them. After an owner has had one experience of the waiting for one sub-contractor after another, and the endless attempts to fix the responsibility for carelessness or bad workmanship, which form the usual accompaniment of building-operations, he is ready to turn with open arms to a contractor who does every part of the work with his own men; and it is not surprising that people of great executive ability, with sufficient capital, should have found advantage in the more comprehensive method of carrying on building business.

AN extraordinary piece of dictation by a labor union is reported from Chicago, where the members of the Coal Teamsters' Union have received orders not to deliver coal to any building where fuel-gas is used during any part of the year in any way. Several teamsters, with coal to deliver, are said already to have driven off with their load on seeing signs of the use of gas in the buildings to which they had been sent. Chicago has already been brought near ruin by union methods, and a greater misfortune could hardly befall the city than a public demonstration of this kind that the tyrants are endeavoring to gain control of its industries again; but it is to be hoped that the contest, which will assuredly follow such a preposterous manœuvre, may be short. It is not denied that the scheme for forcing the people of Chicago to give up the use of fuel-gas was concocted by the officials of the Teamsters' Union in consultation with some, at least, of the great coal-dealers. What return the latter have made, or promised, for the amiable assistance of the unions in promoting the sale of their goods is not stated, but it is not impossible that the facts may be brought out before a court. It is fair to say that we do not believe that all, or even the greater part, of the Chicago coal-operators would stoop to such methods of pushing their business; but it is obvious that the same sort of coercion which is supposed to be valuable in compelling the use of coal in place of gas would be equally available for compelling the use of the particular sort of coal furnished by the friends of the unions. The example of the window-glass trust has shown how effectively the workmen's unions can be used for crushing competing manufacturers, and the demoralization produced by the success of monopoly and coercion in business is so great that we need no longer expect to find any scruples shown as to the means by which control is to be obtained.

A STONE arch of nearly three hundred feet span has just been completed, to connect the beautiful old walled city of Luxemburg with its suburbs. The ancient town stands on a plateau bounded on three sides by almost perpendicular cliffs, more than a hundred feet high, and, after these cliffs had been crowned by Vauban with a fortified wall, Luxemburg was regarded as the strongest place in Europe. Its known strength probably preserved it from assault during the stormy times which followed, and, in 1867, it was peacefully made independent, by agreement of the Powers, and, at present, belongs to the young Queen of Holland, who is also, by inheritance, Grand Duchess of Luxemburg. Like all the other Continental cities, Luxemburg has flourished greatly during the last thirty years of peace, and an extensive suburban quarter has grown up outside the walls. As the new quarter is, however, separated from the old town by a deep valley, it has been necessary to establish communication by some means more convenient than a zigzag path down one cliff and up another; and, some years ago, a fine stone viaduct was constructed. This has now become inadequate, and, a second one being found necessary, M. Séjourné, the distinguished Chief Engineer of the Paris, Lyons and Mediterranean Railway, who was employed by the Grand-Ducal Government, conceived the bold idea of spanning the valley by a single stone arch, by far the widest ever built.

LE GÉNIE CIVIL, which gives an interesting account of the construction of the arch, compares it with the other most important works of the kind. The clear span is two hundred and seventy-seven feet, which is nearly sixty feet greater than that of the Cabin John Bridge, in the District of Columbia, until now the widest stone arch in the world. Bold as the construction is, it has been carried out with great economy. The centring, which was designed by M. Séjourné,

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

consisted, substantially, of a lattice arched girder, tied with wire ropes, and stiffened by a latticed pier in the middle. For the purpose of facilitating the construction, a wooden temporary bridge was built directly over the intended arch, supported by seven latticed towers, and a track was laid on the temporary bridge, so that materials could be brought directly over any part of the arch where they might be wanted. This device was particularly advantageous in permitting the masonry to be carried on simultaneously over every part of the centring, so as to prevent the deformation of the latter by unequal loading, and it proved very successful as a means of economizing labor. The arch was built in three concentric half-rings, or "rowlocks," each rowlock being divided into ten sections by temporary wedges, so arranged that, after the centre was lowered, the wedges could be replaced by permanent arch-stones. The object of this was to preserve a certain elasticity in each ring, so that the settlement, which, with every large masonry arch, follows the striking of the centre, instead of opening the joints, or causing fissures in the masonry, should be taken up by the intervals between the sections, and the subsequent filling of these with stone would leave the arch perfect. It may be observed that the disposition of the arch in three rowlocks would also tend to give it elasticity, and enable it to yield slightly to settlement without fracture, but the idea of carrying out such a construction in three rings of comparatively small stones, instead of making it of a single row of voussoirs of such enormous depth that the curve of pressure could not by any possibility find its way out of the middle third, is rather startling. The result, however, seems to have justified M. Séjourné's reasoning, for the striking of the centre was followed by no alarming result whatever. The completed viaduct is to be fifty-two feet wide, but M. Séjourné reflected that a large sum could be saved in the cost of centring, and a certain additional flexibility secured in the whole structure, by building it of two arches, exactly similar, standing side by side, but connected only by a slab of concrete at the top, forming the roadway. The second arch has not yet been built, but the centring, removed from the first one last October, is ready for setting in its new place, where, as soon as the weather will permit, it will be used for the construction of the second arch.

A CURIOUS story, which may be true, is told about the work which the Westinghouse Electric Company has been doing in England, where it has erected immense shops, at a cost, it is said, of seven million dollars. Before the buildings were begun, bids were invited from English contractors, who set, on an average, five years for the shortest time within which they could be completed. The Westinghouse Company did not like the idea of waiting five years for its shops, and concluded to do the work itself, "on American principles." The agents of the Company bought materials and hired workmen, and the consequences of applying "American principles" to the undertaking was that the shops were completed and ready for use in less than one year from the time the work was begun. Among other things, the speed of British bricklaying failed to please the Westinghouse managers, and, although they held a preliminary conference with the official of the bricklayers' union, and agreed to pay ten per cent more than the union wages, they said plainly that they would not be satisfied with the union standard of four hundred and fifty bricks per day, and would require their men to work according to their capacity. With this view, they appointed inspectors, who made regular returns of the amount of work accomplished by each man. The elimination of the slowest and laziest men through this system produced a wonderful effect on the others, and in a very short time the average day's work of the bricklayers was nine hundred bricks per day. Even this, however, did not satisfy "American principles," and, the same sort of encouragement being continued, it was not long before every bricklayer on the job laid at least eighteen hundred bricks a day, while some, on plain work, laid twenty-four hundred. How the apostles of the "living wage," the "dignity of labor," and the rest of the fine things about which we hear so much, could have looked on in silence at such undignified proceedings as these we cannot understand, and it is not likely that such revolutionary performances will be permitted again in union-ridden England; but, in the meanwhile, all the workingmen, contractors and manufacturers in Great Britain have received a new idea, which may ultimately be of more value to them than the frantic howlings about American and German competition with which they have so long entertained the rest of the industrial world.

THIS story about the success of the Westinghouse Company in getting an honest day's work out of union bricklayers in England is confirmed by a letter to the London *Times*, which says that English bricklayers, where they can escape the eye of the spies of the unions, easily lay two thousand bricks a day, and do the work well, while, as soon as the spy makes his appearance, the men, instead of working steadily and faithfully as before, take up a brick, turn it around two or three times, and lay it down, then take up another and repeat the process, and finally, perhaps, decide to lay a third. In this way it is quite easy for them to reduce their efficiency to the union standard of four hundred and fifty bricks per day, and thus avoid the terrible penalties which the union visits on offending members. Where the unions have succeeded in getting political control of work, as is the case with that executed for the London County Council, which not only employs union men exclusively, but pays them by the day, the inefficiency of the men is positively ludicrous. Many a bricklayer, when working for the London County Council, that is, for the taxpayers of the city, lays, on an average, from one hundred and fifty to two hundred and fifty bricks a day. It is not surprising that the public work of the city, which the union members of the County Council had the effrontery to claim would be more cheaply done in the way that they recommended, cost, in some cases, more than twice as much as responsible contractors, even working with union labor, stood ready to do it for. The *Times*' contributor, who is by no means unfriendly to the unions, and still less to their members, thinks that the condition of British industry is beginning to bring the "friends of the toilers" to their senses, and he mentions a case where some members of a bricklayers' union, who had complained to the officials of a foreman who "badgered" them to work more efficiently than the union rules approved, were severely reprimanded, confronted with the foreman, and made to apologize to him, while he was commended for having done his duty in obliging the men to do a fair day's work.

A GOOD citizen and an intelligent King have quietly undertaken a work of great importance in England. Sir Ernest Cassel, who has before shown a most generous public spirit, on leaving England a few weeks ago for India, put in the hands of King Edward the sum of two hundred thousand pounds, to be expended for such charitable purposes as he might choose. It seems that the King has for a long time been interested in the open-air treatment of tuberculosis, now so firmly established on the Continent, and slowly gaining a foothold in England and in this country, and has decided that no better disposition could be made of Sir Ernest Cassel's money than to use it for providing new sanatoria, where the new treatment may be applied in the most efficient manner to at least a small portion of the multitudes of people who would be benefited or cured by it. It may be observed that, although the Germans possess by far the largest number of these open-air sanatoria, and are entitled to the credit, not only of having first arranged them systematically and efficiently, but of having greatly improved them, the French, with their usual skill in planning, have, within the last two or three years, constructed some admirable establishments; while the Swiss, who have for centuries seen consumptives flocking to the dry air of their mountain resorts, are very little behind. In England, although it is only seven or eight years since the publication of Dr. Burdett's work on hospitals, in which he mentioned the accepted theory of the period, that tuberculous patients should be kept in an even temperature, and protected against draughts of air, several good private sanatoria have been built on the new system; and there are, in this country, a few successful establishments. The experience of all of these will furnish something toward the development of the art of curing the most destructive of all diseases, and, if the King's advisers make use of the information now available, as they undoubtedly will, the noble Cassel gift may be of incalculable benefit to humanity.

THE new Superintendent of Buildings in New York has sent a letter to the President of the Borough of Manhattan, suggesting that the so-called "sky signs," many of which are placed on the roofs of buildings, should be absolutely prohibited. They are so prohibited in England, and the danger, as Mr. Stewart says, that they may blow off and injure people in the streets is so great that they should not be suffered. He makes, moreover, the sensible suggestion that the care and inspection of them should be transferred from the Department of Buildings to the Bureau of Incumbrances, where they obviously belong.

NOTES ON IRON AND STEEL CONSTRUCTION.[1]—III.

HAVING observed the properties, or values, possessed by column and beam sections, it is now in order that the application of these values in practical formulas be demonstrated. Before treating this consideration, however, it is necessary to go somewhat more extensively into the calculations for determining the bending-moment of beams.

This term, as it signifies, is simply the expression of the amount of stress exerted at any point in the length of a beam by the loads upon it. The latter part of the term indicates that the force producing bending is not a direct force, but is a moment of a force; that is, the resulting value obtained when a force acts at a particular point through a lever-arm. For instance, at A in Figure 7 the moment of the force a is equal to the value of a multiplied by the length of the lever-arm and is in this case equal to 300 pounds $\times$ 5 feet, or 1,500 foot-pounds, while at B the moment about c is equal to the

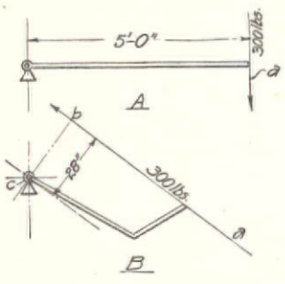

Fig. 7.

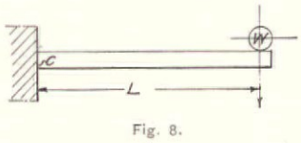

Fig. 8.

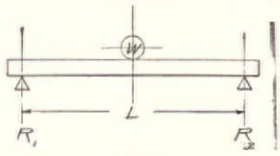

Fig. 9.

value of the force a multiplied, not by the length of the lever-arm, but by the distance $b\,c$, and is, consequently, equal to 300 pounds $\times$ 28 inches, or 8,400 inch-pounds. In this last instance it will be noticed that the distance $b\,c$ is equal to the perpendicular distance from the point c, or the centre-of-moments, to the line of action of the force a. From this it is clear that the moment of any force about any point is equal to the product of the force by the perpendicular distance from the line in which the force acts.

From the two examples just given it will be observed that the bending-moment, or the resultant obtained by multiplying the lever-arm by the force acting at its end, is given neither in units of weight nor length, but in a combination of both, and in whatever unit of length the lever-arm is given, and used as a multiplier, the result must contain this unit in the combined term. So it is that the bending-moment may be expressed either in inch-pounds or foot-pounds, just as the lever-arm is considered. In fact, the bending-moment in plate-girders is often expressed in foot-tons. The values are usually taken in pounds and inches when wooden or steel beams are being considered, and in pounds and feet when a plate-girder is under discussion, the reason for the latter being shown in that portion of the article relating to girders.

By applying these simple principles the usual formula for determining the maximum bending-moment in a cantilever,

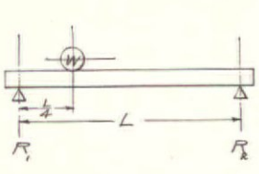

Fig. 10.

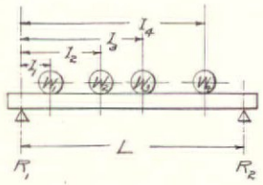

Fig. 11.

that is, a beam supported at one end, is readily evolved. Assume the conditions expressed in Figure 8, and by the principles of moments determine the bending-moment at the point c, at which position it is always maximum in a cantilever. The load equals W, and the lever-arm equals L, consequently, the maximum bending-moment, or M, about c, equals $W\,L$ — or, as it is usually written, $M = W\,L$.

In calculating the bending-moment on any simple beam resting upon two supports, the reactions, or upward thrusts, at the ends must first be determined. The usual method of making the calculations for determining these reactions employs the principle of moments as described. In Figure 9 the beam is supported at both ends, and the reactions, or upward thrusts, at each end of the beam are designated as R_1 and R_2, while the load, which is central, is designated as W. Since the load W is located at the centre of the span, the amount of R_1 and R_2

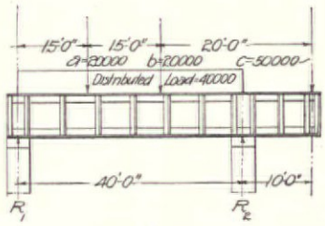

Fig. 12.

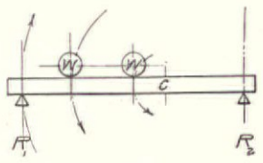

Fig. 13.

is equal in each case to $\frac{1}{2}\,W$, or $\frac{W}{2}$. If the load W had been placed as designated in Figure 10 so that it is one-fourth the length of the span from the left-hand support, or R_1, the farther reaction will amount to one-fourth the entire load on the beam, or $\frac{W}{4}$, while the nearer reaction will be equal to the difference between W and R_2, or three-fourths the load. A fixed law may be evolved from this analysis, which is, that R_2 will always be equal to the sum of the moments of all the loads about R_1, as the centre-of-moments, divided by the span of the beam, or the distance between R_1 and R_2.

In Figure 11 the beam is loaded with the four loads W_1, W_2, W_3 and W_4, which are located at distances from R_1 equal respectively to l_1, l_2, l_3 and l_4; the reaction R_2 may, therefore, be expressed by the following: —

$$R_2 = \frac{W_1 l_1 + W_2 l_2 + W_3 l_3 + W_4 l_4}{L}$$

Besides the foregoing principle, the upward reactions, in order that any beam may be in equilibrium, must equal the downward loads; consequently, if one reaction is determined, the other may be found by subtracting the known reaction from the sum of the loads. This equation may be expressed algebraically as $W = R_1 + R_2$.

When it is required to determine the reaction of a beam loaded with a uniform load, the leverage, or moment of the load, is always considered as the distance from the one reaction, which is the centre-of-moments to the centre-of-gravity of the uniform load. A practical example may tend to make these principles clear, so the following is taken: A plate-girder of the dimensions shown in Figure 12 is loaded as designated, with concentrated and uniform loads, the problem being to determine the reactions, or R_1 and R_2.

Let R_1 equal the centre-of-moments; then the moments of the several loads about this point will equal

Uniform load	$= 40{,}000 \times 20 =$	800,000 foot-pounds.
Load a	$= 20{,}000 \times 15 =$	300,000 foot-pounds.
Load b	$= 20{,}000 \times 30 =$	600,000 foot-pounds.
Load c	$= 50{,}000 \times 50 =$	2,500,000 foot-pounds.
Total	$=$	4,200,000 foot-pounds.

And $4{,}200{,}000 \div 40 = 105{,}000$ pounds, which is the amount of the reaction R_2. Since the sum of the loads, therefore, must equal the sum of the reactions, and as the sum of the loads in this case equals 130,000 pounds, and as R_2 equals 105,000, R_1 must equal 130,000 — 105,000, or 25,000 pounds.

The principles for finding the reactions, just explained, are largely employed in calculating the reactions at the ends of beams and girders employed in a riveted structure, so that the connections may be designed, and in determining the pressure coming upon a pier or abutment from a beam or girder when

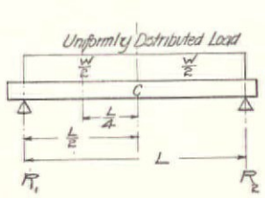

Fig. 14.

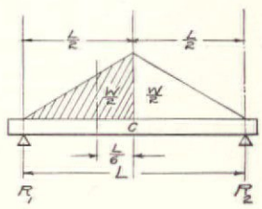

Fig. 15.

the loads are unequal or not symmetrically placed. It is necessary also to determine the reactions before the bending-moment can be figured, as will be explained.

[1] Continued from No. 1360, page 21.

When a beam is subjected to transverse or bending stress the loads act in a downward direction around any point in the beam with a moment equal to their amount by their distance from the point in question, while the reactions act in an upward direction with moment equal to their distance from the

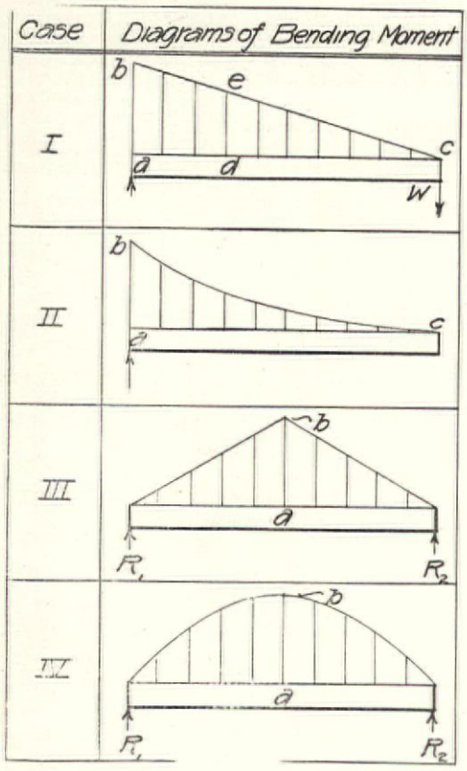

Fig. 16.

same point, or centre-of-moments. Figure 13 makes this clear by the graphical representation of the several loads and reactions acting in opposite directions about the point *c*.

In Figure 9 the load W is shown supported at the centre of the beam with a span equal to L. The reaction R_1 in this figure is equal to $\frac{W}{2}$ and the moment of R_1 about W is equal to $\frac{L}{2}$, consequently, the bending-moment at c is equal to $\frac{W}{2} \times \frac{L}{2}$, or $\frac{WL}{4}$, which is the usual expression for the bending-moment of a beam supported at both ends and sustaining a concentrated load at the centre of the span.

The formula for the bending-moment for the beam loaded with a uniform load as shown in Figure 14 may be likewise determined. For instance, let W equal the uniform load; then R_1, as before, equals $\frac{W}{2}$, and the lever-arm of R_1 about c equals $\frac{L}{2}$; in consequence, the moment of R_1 about c equals $\frac{W}{2} \times \frac{L}{2}$, or $\frac{WL}{4}$; but the half of the uniform load to the left of c opposes the upward moment of the reaction R_1, with a leverage equal to $\frac{L}{2}$ divided by 2, or $\frac{L}{4}$, and the opposing moment equals $\frac{W}{2} \times \frac{L}{4}$, or $\frac{WL}{8}$; then deducting from $\frac{WL}{4}$ the moment of R_1, $\frac{WL}{8}$, the opposing moment of the load, the result becomes $\frac{WL}{8}$, which is the formula for a uniformly loaded beam. The general statement that the bending-moment is equal to the algebraic sum of the moments due to the external forces acting on the beam is true of any beam.

It is not uncommon for a beam to be loaded with a triangular load, and the determination of the formula for finding the maximum bending-moment is quite as simple as those explained in the two previous examples. Figure 15 shows a beam or girder supporting a triangular load, such as would require the support of a beam or girder over an opening in a brick or stone wall. In this case the reaction R_1 equals $\frac{W}{2}$, and the moment of the reaction about the centre c of the beam is equal to $\frac{W}{2} \times \frac{L}{2}$, or $\frac{WL}{4}$. The centre-of-gravity of the triangular load as section lined and which acts with a moment negative, with respect to the moment of R_1 about c, is located at a distance of one-third of the half-span, or $\frac{L}{6}$ from the centre c. The downward moment of the load about the point c — that is, the negative moment with reference to the reaction R_1 — equals then $\frac{W}{2} \times \frac{L}{6}$, or $\frac{WL}{12}$, and the maximum bending-moment which occurs at the centre of the girder equals the algebraic sum of the positive moment of R_1 about the point c and the negative moment of the half load about the same point, which may be expressed as $M = \frac{WL}{4} - \frac{WL}{12}$, or, simplified, $M = \frac{WL}{6}$.

It is seldom necessary to determine the bending-moment at different points in the length of a girder, but where such is the case a graphical solution is probably the most convenient, and at least shows clearly the action of the loads upon simple beams.

Take, for instance, the simplest case of loading, Case I in Figure 16. Here the bending-moment $M = WL$; then the distance $a\,b$ is laid off equal, by any scale, to the bending-moment M in foot- or inch-pounds, as the case may require. From the diagram the bending-moment may be obtained at any point throughout the length of the beam by drawing the line $b\,c$ and scaling the ordinate at the point in question; that is, if the bending-moment is required at the point d, measure the ordinate $d\,e$ with the same scale used in measuring $a\,b$, and the bending-moment at the point in question is readily obtained. In Case II, which shows a cantilever beam loaded with a uniformly distributed load, the bending-moment is represented graphically by the parabola $b\,c$; $a\,b$ as before is laid off equal to the bending-moment, which is obtained algebraically by the principle of moments as previously described, and is equal to $\frac{WL}{2}$. From the length of the several ordinates, the bending-moment at the several points throughout the length of the cantilever may be obtained.

Likewise in Case III, the bending-moment on the beam supported at both ends, and loaded with a concentrated load at the centre, is represented in its action throughout the length of the beam by the triangle which has for its ordinate the distance $a\,b$ made to represent by scale the bending-moment at the centre of the span, and for its base the length of the span.

Where the beam is uniformly loaded, as designated in Case IV, the uniformly distributed load upon the beam supported at both ends is always represented graphically by the parabola which has the distance $a\,b$ for its greatest ordinate, and which equals to scale the maximum bending-moment, or $\frac{WL}{8}$. The fact that a uniformly distributed load on a girder can be represented in this way is valuable in the design of plate-girders, for upon this principle is founded the graphical method of determining the length of the several flange-plates, and, indeed, a similar means of determining the rivet-spacing in the flange-angles may be employed. These several applications of this principle will be given under the subject of plate-girders.

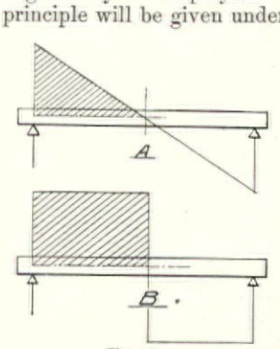

Fig. 17.

As may have been observed, the bending-moment on any beam varies, and attains its maximum value at some point usually determined by trial. The point of greatest bending-moment is always at the point where no shear occurs on the beam.

The loads on a beam act in an opposite direction to the reactions, and the tendency of these opposing forces to shear through the section of a beam is called "shear." The greatest shear on a beam occurs at the abutment at which the greatest reaction takes place. Where a beam is uniformly loaded the shear is greatest at the reactions, and diminishes uniformly to the centre, where it is zero, but where a beam is loaded with a single concentrated load at the centre, the shear is uniform throughout the girder, and is equal to one-half of the concentrated load, or the amount of one of the reactions. These two

conditions prevailing under the different systems of loading are clearly shown in Figure 17 where at A is designated graphically the effect of the shear and its uniform variation from the

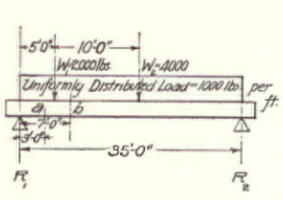

Fig. 18.

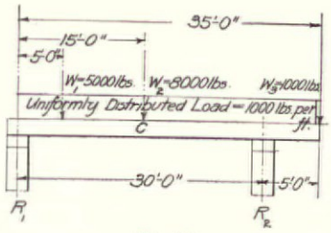

Fig. 19.

abutment to the centre, while at B is designated the uniformity of the shear throughout the beam.

The shear at any point throughout the length of a beam, no matter how loaded, is equal to the algebraic sum of the loads and the reactions. That is, the shear at any point is equal to the reaction at either abutment minus the sum of all the loads supported upon the beam between that reaction and the point in question. With reference to Figure 18, the reaction R_1 equals 21,500 pounds; the shear at point a equals 21,500 pounds minus 3,000 pounds, which is the uniform load to the point in question, or 18,500 pounds; the shear at b on the beam in question is equal to 21,500 pounds minus 7,000 pounds, the portion of the uniform load from the abutment to the point b, plus the concentrated load W_1 of 2,000 pounds, or 12,500 pounds.

If this subtraction of the loads was continued the reaction R_1 would finally be absolved and the shear would equal zero — that is, it changes from a positive to a negative quantity, and the shear is said to change signs. At this point, where the shear equals zero, or where it is said to change signs, exists the greatest bending-moment. When the beam supports a

Table of Formulas for Bending Moments

Method of Loading Lengths in inches Loads in Pounds	Bending Moment Inch-Pounds	Reactions Pounds
	WL	W
	$\frac{WL}{2}$	W
	$\frac{WL}{4}$	$\frac{W}{2}$
	$\frac{WL}{8}$	$\frac{W}{2}$
	$\frac{WL}{6}$	$\frac{W}{2}$
	$\frac{Wa}{2}$	$\frac{W}{2}$
	At either support $\frac{Wa^2}{2L}$ At center of Span $\frac{W}{2}(a-\frac{L}{4})$	$\frac{W}{2}$

number of concentrated loads, or an uniformly distributed and a number of concentrated loads, the shear usually changes signs under one of the concentrated loads. At this point the greatest bending-moment occurs, and the particular load is the first one which, together with the loads lying between it and the abutments, equals or exceeds the amount of the reaction. For example, the beam shown in Figure 19 overhangs one of the supports, and is loaded with a uniformly distributed load and several concentrated loads. The reaction R_1, considering the moments about R_2, is calculated as follows: —

Moment of uniform load	$35 \times 1{,}000 \times 17.5$	$= 612{,}500$
Moment of W_1	$5{,}000 \times 5$	$= 25{,}000$
Moment of W_2	$8{,}000 \times 15$	$= 120{,}000$
Moment of W_3	$1{,}000 \times 35$	$= 35{,}000$
Summation of moments		$= 792{,}500$

and R_2 equals $792{,}500 \div 30$, or 26,416 pounds, and R_1 equals the sum of the loads, or 49,000 minus 26,416, or 22,584 pounds. Taking R_1, then, at this figure, it is evident that the loads up to and including W_1 will not absorb it entirely, but that the load to and including W_2 will be more than sufficient, as they will amount to 15,000, the uniform load plus W_1 and W_2, respectively, of 5,000 and 8,000 pounds, or 28,000 pounds; under the load W_2, therefore, will the greatest bending-moment take place. It is, consequently, necessary to determine the negative and positive moments about the point c directly under the concentrated load W_2. The moment of the reaction R_1, or the positive moment, as it may be called, equals $22{,}584 \times 15$, or 338,760, while the negative moment, as the sum of the moments of the loads between c and R_1, about c or W_2, may be called, is found to equal

$$\begin{aligned} 15{,}000 \times\ 7.5 &= 112{,}500 \\ 5{,}000 \times 10\ &= 50{,}000 \\ \text{or, } &162{,}500 \end{aligned}$$

so that the greatest bending-moment is the difference between the negative moments of the loads about c and the positive moment of R_1 about the same point, or $338{,}760 - 162{,}500$, which gives 176,260 foot-pounds, the greatest bending-moment on the beam, and the desired result.

By these means the bending-moment of any girder may readily be determined, and the shear, likewise, at any point, obtained. Through the table entitled "Table of Formulas for Bending-moments," the transverse stress upon any simple beam may be conveniently calculated. M. M. Sloan.

[To be continued.]

THE DEPARTMENT-STORE RISK.

From a paper in the *Chronicle* by Messrs. De Lemos and Cordes, architects, of New York, we make the following interesting extract: —

"Taken all in all, the department-stores, individually and as regarding fire-insurance risks, may be said to be practically in a class by themselves. The schedules of the New York Fire-insurance Exchange cannot reasonably and to the full extent be applied to such huge structures, and, therefore, contingencies of construction that would cause a given increase or decrease of insurance-rates in ordinary sized buildings do not always cause the same effect in such cases. Clear and concise, though probably not always logical, as the schedules are where buildings of ordinary size are concerned, varying circumstances will modify or even increase the rigor where such exceptional fire-risks are to be encountered. Therefore, the architect has to exercise good judgment and great care in planning his building so as to meet the necessary conditions of occupancy and the very important factor of saving on insurance-rates both to building and merchandise. It will thus be of advantage to combine stairways and elevators at their various locations and to surround them and a hallway in front entirely with iron framework, plaster, and wire plate-glass partitions. The plate-glass will not obstruct the view, and the plaster surfaces of the partitions will be provided near the ceiling, serving as a fire-screen. All can be handsomely developed and ornamented so as to look attractive and cheerful, at the same time giving full security against spread of fire, and having the further great advantage that each stairway is a perfect and safe fire-escape. Facings of marble or metal may be substituted for the plastered surfaces. The doors leading into the hallways should be fireproof and close automatically. Rolling shutters, to be used at night, should be provided in addition.

"It will be found that the rear end of such buildings will have to be given up to receive and ship goods, to house and take care of the employés, to place the large stacks serving the purpose of heating and ventilation; therefore, it will suggest itself, if possible, to separate this portion of the building from the main building by fireproof walls and fireproof doors. The advantage is, that the area of fire-spread is effectually reduced and thereby the fire-risk is substantially lessened. At the same time it is a most perfect fire-escape either way on each floor to the public and employés by permitting the people to descend in safety the stairways in a separated building not affected by smoke or fire. The large freight-elevators, conveyors for merchandise, dumb-waiters, and similar apparatus, which would naturally be

located in this part of the building, should all be inclosed in fireproof walls or partitions, and have solid or kalamined iron doors.

"A great difficulty is always encountered in large establishments in providing proper and convenient access and egress to lunch-rooms and lockers for the great number of employés. The most economical place generally appears to be on the top floor, which, however, in large establishments, is not advisable, embodying, as it does, a great danger in case of fire. Besides, as all employés come and leave at the same time, it is almost impossible to provide for adequate elevator facilities. Supposing there were 4,000 employés and four elevators accommodating forty people each; figuring four minutes for a round-trip, say, of 135 feet travel, it would require twenty-five trips for each elevator, or one hour and forty minutes, to move this number of people either way. Coming and going in the morning and evening and, figuring only one return trip for taking lunch, would be four trips for each person. This represents 100 trips for each elevator or 400 trips for one elevator, equal to a travel of 54,000 feet, or an energy equal to lifting 2,000,000 pounds 135 feet high. In figuring the financial side of this question, aside from the almost insurmountable practical objections, it will be seen that the best results will be obtained by providing the necessary space in an annex or sacrificing the required space on one of the lower floors, which could be reached without the use of elevators, by means of commodious stairs provided for the purpose; at the same time reducing the risk in case of fire to a minimum.

"A necessary provision in all large stores is the arrangement of two waste chutes, which convey all refuse from the various floors to a fireproof inclosed room in the basement or cellar — one for paper, cardboard, etc., to be sold, and the other for refuse to be burned. As all this refuse is highly inflammable, consisting mostly of paper, broken boxes, or similar matter, especial care is needed to prevent the spread of fires through these chutes. Therefore, in every story a receiving-box of boiler-iron, with double iron trap-doors, should be provided, connecting with a main shaft constructed of brick, preferably of boiler-iron, forming the chute. These trap-doors are balanced so as to open and close automatically as soon as the waste has been dropped into the box, and in such manner that, as one door is opened, the other door closes. Arriving at the basement or cellar, the refuse is conveyed thence to the boilers and cremated or otherwise disposed of as stated. The chutes themselves are located within a suitable fireproof inclosed closet with self-closing doors.

"Whether the floors themselves, as they are to be placed on the fireproof-floor arches of concrete or ash-filling, consist of wood or of tile (mosaic) or other material will make little difference as to the fireproof character of the construction. The finished floor is in any case placed on a solid foundation of concrete or other fireproof filling-material, not permitting any air to circulate underneath, and, therefore, making it improbable that a wood floor could be exposed to fire to any dangerous extent. There are several patent compositions offered, such as alignum, asbestolith, lignolith, and others, as substitutes for wooden flooring. For all of these, fire-resistance is claimed. As a matter of course, all woodworks, such as window-casings, base-boards, and door-trimmings, will necessarily be reduced to the least possible limit, or where, for appearance sake, wainscotings or similar decorative finish is to be employed, the same will be of marble, slate, metal, or fireproof wood.

"The location and insulation of the boiler-room, engine-room, of the electric, heating and ventilating machinery, with all their numerous ducts and complicated system of piping, fitting and wiring, are a further subject for careful consideration. That part of the building which is to receive this extensive, complicated, and costly plant must be also completely separated by fireproof walls, and all duct or similar work carrying heated air, electric mains, and steam or hot-water pipes, where passing into the various floors of the building, must be carefully insulated and protected against fire or against spreading or originating fire.

"As to the construction of the façades of the building, the material to be selected is of slight consequence where the building is of the steel-framed type. It is actually not much more than a veneer incasing the metal structure, brick and terra-cotta being, of course, the most fire and weather resisting. Cornices would be preferably of metal (copper, steel, cast-iron, or galvanized iron) instead of stone or terra-cotta, as being light of weight and, therefore, less dangerous than heavy and far-projecting cornices of solid material would be.

"Owing to the uncompromising demands for direct daylight at all floors, the elevations are naturally a combination of piers, metal, and glass. Therefore, a thorough and efficient protection of the fronts against fire does not seem feasible. Such large stores generally face on streets of ample width, and, therefore, the danger of fire eventually to be communicated by buildings fronting them on opposite street-sides is not very great. Devices could undoubtedly be introduced whereby, in such an emergency, the front walls could be flooded or protected by a sheet of water falling over them in a similar manner, as the inside floors of the building receive additional protection through the automatic-sprinkler systems. There seems, however, no case on record where such provision has actually been resorted to, and its effect might be doubtful, owing to the action of heat and water on the large glass surfaces. In almost any case, where damage to buildings from sources herein under consideration occurs, the actual destruction by fire is much less than that caused by water. The contents of all large stores are, as a matter of course, protected against general destruction by automatic sprinklers. As soon as the fire sets them in partial operation great quantities of water are discharged on the floors, penetrate through them, destroying the plastered ceilings, causing wooden floor-boards to warp and damaging merchandise. In addition, the powerful engines of the fire-department, when called in, will send a further deluge into the endangered parts of the building, gutting and ruining all there is contained in that part of it. In many warehouses, therefore, steps are taken to make the floors not only thoroughly waterproof, but to grade them to gutters with inside and outside leader connections. These leaders, of ample section, will rapidly carry off the water to the street sewers and thus prevent great, and sometimes unnecessary losses. The inconvenience of not having even floor-levels renders such arrangements objectionable in department-stores, where the greatest public comfort must be provided, and level surfaces are needed to fit properly the counters and other installations.

"The automatic-sprinkler systems, valuable as they are for checking the spread of fire, and thus insuring a large reduction in the insurance-rates, are, nevertheless, a matter of great discomfort to the architect. Not only is the placing of the enormous tanks, machinery, and piping required to operate the systems for an effective distribution, a complex problem in itself, but the numerous lines of suspended pipes and conductors naturally interfere more or less with any attempt at architectural ceiling-decoration or other effects. Hence, as in many other cases in the architect's profession, utility outweighs the demands of design and art.

"In conclusion, it may be said that the close and continuous study given to an effective fire-protection by architects, by engineers, by the fire-insurance companies, and by the owners themselves, carries with it ever increasing results for the better, as will be readily observed when comparing buildings of recent date with those erected not more than a decade ago. Therefore, it may be reasonably hoped that the appalling losses of property from this source, reduced already by a gratifying percentage through careful building, will yet be lowered very materially, and in the near future." — *The Chronicle.*

A LETTER OF MAJOR L'ENFANT'S.

GAILLARD HUNT, the historian of the Department of State, has raked the files of that Department and prepared a "Calendar of Applications and Recommendations for Office during the Presidency of George Washington." Among the data thus gathered is a letter from L'Enfant to President Washington, which is here reproduced, errors and all, as it throws a most interesting light on a variety of subjects just now engaging public attention:

"NEW YORK *Septbr the* 11*th* 1789.

"SER

"The late determination of Congress to lay the foundation of a city which is to become the Capital of this vast Empire, offer so great an occasion of acquiring reputation, to whoever may be appointed to conduct the execution of the business, that your Excellency will not be surprised that my Ambition and the desire I have of becoming a usefull Citizen should lead me to wish a share in the undertaking.

"No Nation perhaps had ever before the opportunity offered them of deliberately deciding on the spot where their Capital city should be fixed, or of combining every necessary consideration in the choice of situation — and altho' the means now within the power of the country are not such as to pursue the design to any great extent, it will be obvious that the plan should be drawn on such a scale as to leave room for that aggrandizement & embellishment which the increase of the wealth of the nation will permit it to pursue at any period however remote — viewing the matter in this light I am fully sensible of the extent of the undertaking and under the hope of a continuation of the indulgence you have hitherto honored me with I now presume to solicit the favor of being Employed in this Business.

"And now that I am addressing your Excellency I will avail myself of the occasion to call to your attention an object of at least equal importance to the dignity of the Nation, and in which her quiet and prosperity is intimately connected. I mean the protection of the Sea Coast of the United States — this has hitherto been left to the Individual States and has been so totally neglected as to endanger the peace of the Union for it is certain that any insult offered on that side (and there is nothing to prevent it) however immaterial it might be in its local effect, would degrade the nation and do more injury to its political interests than a much greater depradation on her Inland frontiers from these considerations I should argue the necessity of the different Ways and seaports being fortified at the expense of the union in order that one general and uniform system may prevail throughout, that being as necessary as an uniformity in the discipline of the Troupes to whom they are to be Intrusted.

"I flater myself your Excellency will excuse the freedom with which I impart to you my ideas on this subject indeed my Confidence in this Business arises in a great measure from a persuasion that the subject has already engaged your attention, having had the honor to belong to the Corps of Engineer acting under your orders during the late war, and being the only officer of that Corps remaining on the Continent I must confess I have long flattered myself with the hope of a reappointment a hope which was encouraged by several individuals of the former Congress — and now when the establishment of a truly federal Government renders every post under it more desirable, I view the appointment of Engineer to the United States as the one which could possibly be most gratifying to my wishes and

tho' the necessity of such an office to superintend & direct the fortifications necessary in the United States is sufficiently apparent, the advantage to be derived from the appointment will appear more striking when it is considered that the sciences of Military and Civil architecture are so connected as to render an Engineer equally serviceable in time of Peace as in war, by the employment of his abilities in the internal improvement of the Country.

"Not to intrude any longer on your patience and without entering on any particulars relating to my private circumstances of which I believe you are sufficiently informed I shall conclude by assuring you that ever animated as I have been with a desir to merite your good opinion nothing will be wanting to compleat my happiness if the remembrance of my former services connected with a variety of peculiar circumstances during fourteen years residence in this Country can plead with your Excellency in support of the favour I solicite.

"I have the honor to be with profound respect your Excellency

"Most humble and

"obedient servant

"P. C. L'ENFANT.

"THE PRESIDENT OF THE UNITED STATES."

GREAT CANALS OF THE WORLD.

"GREAT Canals of the World" is the title of a study prepared by the Treasury Bureau of Statistics for publication in the forthcoming volume of the *Monthly Summary* of *Commerce and Finance*. It shows the commerce, cost and dimensions of the great canals of the world, especially those connecting great bodies of water, and which may be properly termed ship-canals.

Ship-canals connecting great bodies of water and of sufficient dimensions to accommodate the great modern vessels plying upon such waters are of comparatively recent production and few in number. The one great example of works of this character which has been a sufficient length of time in existence and operation to supply satisfactory data as to cost of maintenance and operation and practical value to the commerce of the world is the Suez Canal, and for this the available statistics begin with the year 1870, while its new and enlarged dimensions only date from the year 1896. For the Sault Ste. Marie Canal, connecting Lake Superior with Lake Huron, statistics date from 1855, though for the canal in its present form they cover only about four years. Statistics of the Welland Canal date from 1867, but for the canal in its present enlarged form cover only two years of operation. The other great ship-canals of the world are of much more recent construction, and data regarding their operation therefore cover a comparatively brief term, and in some cases are scarcely at present available in detail.

The artificial water-ways which may properly be termed ship-canals are nine in number, viz: —

1. The Suez Canal, begun in 1859 and completed in 1869.
2. The Cronstadt and St. Petersburg Canal, begun in 1877 and completed in 1890.
3. The Corinth Canal, begun in 1884 and completed in 1893.[1]
4. The Manchester Ship-canal, completed in 1894.
5. The Kaiser Wilhelm Canal, connecting the Baltic and North seas, completed in 1895.
6. The Elbe and Trave Canal, connecting North Sea and Baltic, opened in 1900.
7. The Welland Canal, connecting Lake Erie with Lake Ontario.
8 and 9. The two canals, United States and Canadian, respectively, connecting Lake Superior with Lake Huron.

The description which is given of each of these great water-ways shows that the total length of the Suez Canal is about 90 miles, the cost $100,000,000, the present depth 31 feet, width at bottom 108 feet and at the surface 420 feet, and that the number of vessels passing through it has grown from 486 in 1870 to 1,494 in 1875, 2,026 in 1880, 3,389 in 1890, and 3,441 in 1900. The tolls charged are about $2 per net registered ton.

The Cronstadt and St. Petersburg Canal, which gives a passage-way for great vessels to St. Petersburg, is 16 miles long, including the deepening of the bay channel, 20½ feet in depth, and the total cost estimated at $10,000,000.

The Corinth Canal, which connects the Gulf of Corinth with the Gulf of Ægina, is 4 miles in length, 26¼ feet in depth, 72 feet wide at the bottom, cost about $5,000,000, and reduces the sailing distance about 175 miles. The average tolls charged are 18 cents a ton and 20 cents a passenger.

The Manchester Ship Canal, which connects Manchester, England, with the Mersey River and Liverpool, was opened in 1894. Its length is 35½ miles, depth 26 feet, width at bottom 120 feet and at the surface 175 feet, and cost $75,000,000. The commerce on the canal shows a growth from 879,204 tons in 1895 to 1,492,320 tons in 1900.

The Kaiser Wilhelm Canal, which connects the Baltic and North seas through Germany is 61 miles in length, 29½ feet in depth, 72 feet wide at the bottom, 190 feet wide at the surface, and cost about $40,000,000. The number of vessels passing through it has increased from 19,960 in 1897 to 29,095 in 1900, of which number 16,776 were sailing-vessels. The tonnage in 1897 was 1,848,458, and in 1900, 4,282,094 tons. An additional canal, connecting the same bodies of water by way of the Elbe and Trave rivers, was opened in 1900. Its length is 41 miles, depth about 10 feet, width 72 feet and cost $6,000,000.

The great North Holland Canal, which connects Amsterdam with the sea, cut in 1845, but deepened at a later date, has now a depth of 20 feet, and a width of 125 feet at the surface. The Caledonian Canal, which connects the Atlantic and North Sea through the north of Scotland, is 17 feet in depth, 50 feet in width at the bottom, 250 miles long, cost $7,000,000, and is at its highest point 94 feet above sea-level. The Canal du Midi, cut through France from Toulouse, on the Garonne, to Cette, on the Mediterranean, a distance of 150 miles, is 6½ feet deep, 60 feet wide and 600 feet above sea-level at its highest point, and has 114 locks; total cost, $3,500,000.

In America the canals connecting the Great Lakes are the principal ship-canals, and are three in number: The Welland Canal, originally constructed in 1833 and enlarged in 1871 and 1900; the Sault Ste. Marie, or St. Mary's River, Canal, opened in 1855 and enlarged in 1897, and the Canadian Canal at St. Mary's River, opened in 1895. The American and Canadian canals at St. Mary's Falls are practically identical in location and dimensions, and are used interchangeably by vessels engaged in commerce, as convenience may dictate. The depth of the canals at the St. Mary's River is sufficient to accommodate vessels drawing 20 feet of water. The American canal was originally constructed by the State of Michigan, but subsequently was taken charge of by the United States and enlarged, at a cost of $2,150,000. The cost of the Welland Canal was about $30,000,000, which was largely due to the circumstance that 25 locks are required in surmounting the rise of 327 feet in the distance of 27 miles. The number of vessels passing through the canals at St. Mary's River has greatly increased during the last few years, while the number passing through the Welland Canal has materially decreased, the number passing through the St. Mary's canals being, in 1873, 2,517, and in 1901, 20,041, of which 15,837 passed through the United States Canal and 4,204 through the Canadian. The number of vessels passing through the Welland Canal has decreased from 6,425 in 1873 to 2,202 in 1899. The marked contrast between the business of the St. Mary's Falls and Welland canals is largely due to the fact that the freights originating in the Lake Superior district are chiefly discharged at Lake Erie ports, and those destined for the Lake Superior region are chiefly produced in the section contiguous to Lake Erie, the Lake Superior freights being chiefly iron, copper and grain, and the Lake Erie freights for Lake Superior, coal and manufactures. The business of the St. Mary's Falls canals by far surpasses in volume that of any other canal of the world, the freight tonnage of the American and Canadian canals combined being, in 1901, 24,626,976 registered tons, while the net tonnage of the Suez Canal in 1900 was 9,378,152 tons, and that of the Kaiser Wilhelm Canal 4,282,094 tons.

[1] The modern work was begun in 1882, while work was first actually undertaken by Periander B. C. 625. — EDS.

NOTES & CLIPPINGS

City Contractor's Liability for Blasting. — The N. Y. Court of Appeals has reversed an order of the Appellate Division which reversed a judgment dismissing the complaint in a suit brought by the company which owns the Holland House, at the southwest corner of Fifth Avenue and Thirtieth Street, against William P. Baird to recover damages for injuries to a vault in the hotel, caused, as alleged, by the negligent blasting of rock in a trench which was being dug in Fifth Avenue by the defendant for the city. The contract between Baird and the municipal authorities called for the blasting of rock, and required it to be done according to the city ordinances. The occurrence complained of happened in August, 1897. The damage to the vault was described on the trial by barbers employed in the hotel, and by a brush-boy. While the trench was being dug they "heard a good many sounds as of blasting." The brush-boy, while not remembering the day, "heard one sound which impressed itself on his mind; it was a big blast." None of the witnesses identified Mr. Baird as the contractor, or as causing the blasts. A civil-engineer testified about explosives, but knew nothing about the quality of the rock in front of the Holland House. The Court of Appeals holds, by Judge Gray, that, under the circumstances, Mr. Baird could only be held liable for injury to adjoining property from the jarring of the ground or concussion of the atmosphere, on proof that his work was negligently performed. "The rule of law," says Judge Gray, "must, therefore, be considered as well settled in this Court that negligence is essential to be proved in such a case as this of consequential injury, in order to create any liability in the defendant. Now, there is nothing in the evidence showing, or tending to show, the fact of a negligent performance by the defendant of what blasting was rendered necessary in the execution of his contract. Indeed, the evidence is so vague upon the subject that it is not certain whence the blast or blasts, of which the witnesses speak, came. If it may be inferred that the defendant was excavating upon the west side of Fifth Avenue, it does not appear where, or how wide, the trench excavation was, or what was its distance from the wall of the vault. The manner of the construction of the vault, whether well or slightly built, is not shown. Nor is there anything to show, considering the circumstances, that the blast was of any extraordinary character, or that its violence was manifested in external ways upon the street. . . . It was a matter of conjecture, purely, whence the blast came which occasioned the damage to the property; what was the nature of the trench, or what the quality of the soil in which the work was being done, or whether the defendant, in conducting the necessary blasting, failed to observe the ordinances of the city upon the subject and neglected to use such care as was incumbent upon him with respect thereto, or to the adjacent property. In short, for aught that appears, the defendant may have taken all those precautions incumbent upon him, in the performance of such a work, and, nevertheless, the damage may have happened to the plaintiff's building as a natural result, influenced, possibly, in addition, by some weakness of construction." The court of last resort was unanimous, but the Appellate Division divided, Presiding Justice Van Brunt and Justices Patterson and Rumsey favoring the maintenance of the action, and Justices O'Brien and Ingraham dissenting. J. Woolsey Shepard argued the case for Mr. Baird, and Aaron C. Thayer represented the Holland House Company. — *Exchange.*

P. Troubetzkoy, the Sculptor. — Paul Troubetzkoy was born at Intra, Lago Maggiore, on the 15th of February, 1866, the second son of Prince Pierre and Princess Ada Troubetzkoy (*née* Winans). The delight of the child was to model; using first soft bread, then later, at the age of seven, being allowed modelling wax to play sculptor. He chose for his first model an old beggar whom he chanced to find outside the villa gates, and whom he paid with fruit saved from his own dessert. From this beginning, always encouraged by his mother, he continued to model from life, his pets and other domestic animals serving as subjects, until, at ten years of age, he was so successful with the head of a horse that his mother, realizing that the child was becoming serious in his work, took the head to Milan for the criticism of the sculptor Grandi. Looking at it carefully, Grandi pronounced it the work of genius, and said that the boy if he worked on was destined to become a famous sculptor. This prediction did not meet with the approval of Prince Troubetzkoy, whose ambition for this son was a military career, the eldest having been already granted permission to study art, as he showed a decided talent for portraiture. Accordingly, at the age of seventeen, the young sculptor was sent to his paternal relatives in Russia, with the hope that under new influences the youth might be made to forget his hobby. But the power of calling was too great. The allurements of a high military career failed to turn him, and after some months' absence he returned to Italy. Finding that he could not follow others, however great they might be, Paul Troubetzkoy began working according to his own particular light; he opened a studio of his own; toiled with all his might, deaf to the criticism of friend or foe; and he so impressed both public and critics that it was finally acknowledged that a new star had arisen, the magnitude of which it was at first difficult to measure. — *From "Paul Troubetzkoy, Sculptor," by William Jarvis, in the February Scribner's.*

Opposition to "Skyscrapers" in Chicago. — On a test vote recently the City Council blocked temporarily the construction of eight skyscrapers. The plans included seven sixteen-story and one fourteen-story buildings. The amount of money which the builders of these structures expect to spend on them is about $12,000,000. The principal opposition against the big buildings came from outlying districts, which have always opposed the erection of high structures in the business district on the plea that they tend to congest all trade in the down-town territory. — *Exchange.*

Babylonian Discoveries of the German Oriental Society. — The members of the Babylonian expedition sent out by the German Oriental Society have, in spite of heat, wind and dust, held out steadfastly at their post, and have brought to light many valuable memorials which, with those already unearthed, will some day give a faithful picture of the ancient metropolis, its streets, temples and palaces, and its social, intellectual and religious life. Up to now four hundred inscribed clay slabs have been found in the centre of the ruins of Babylon. Of only two of them are the inscriptions yet deciphered, but they are pearls of Babylonian literature. One tablet contains a great part of a celebrated Babylonian compendium which explains the Babylonian cuneiform characters. It is a very ancient dictionary, of great linguistic interest and of exceptional value practically. The second tablet contains nothing less than the litany which was chanted by the singers of the Temple of Esagila on the return of the god Marduk to his sanctuary. Marduk, or Merodach, was the son of Ea, and one of the twelve great gods of the Assyro-Babylonian Pantheon. His temple, Esagila, "the exalted house," became the national sanctuary of the whole empire. He also had a sanctuary at Sippar. He is twice mentioned in the Book of Jeremiah, and in Isaiah, as Bel. It was the custom to sing the litany which has now been found after the periodical procession to that grand pantheon which has been brought to light by the expedition, and which, it is hoped, by the winter will be completely excavated. In the meantime Herren Koldewey and Andrae have made another important discovery, a temple of Ador, or Nineb, the tutelar god of physicians, hitherto quite unknown. The German Oriental Society's account of these discoveries, which has just been published, also gives a minute description of an amulet, supposed to protect the wearer from the machinations of the demon Labartu. Labartu was an ashen-hued being, who made people pale with terror, drank human blood, caused great sorrow, and was accompanied by a black dog. This amulet was once hung around a child's neck in order to drive off the demon. — *London News.*

A Porcelain Tower for Paris. — A Sèvres porcelain tower is to be erected on the heights of St. Cloud, the spot where the famous Diogenes lantern was destroyed in 1871. The tower will be 148 feet high and 26 feet in diameter. There will be seven stories and a double winding staircase inside. It will be built, inside and out, entirely of ceramic stoneware and porcelain, and will be decorated externally with blue, turquoise, emerald-green, brown, coral and rose tints on a white porcelain background. The colors will be a perfect polychromatic poem from base to summit, idealizing the fauna and flora and legends of the Forest of St. Cloud. The work is about to be begun at the State manufactory at Sèvres. The tower will be composed of thirty thousand pieces, which will require a hundred bakings. It will be completed in five years. — *N. Y. Tribune.*

The Asphalt Supply. — In a paper read recently before the American Society of Municipal Improvements, J. Howard Bell, C. E., engineering-editor of the *Municipal Journal*, said: "The European companies have not used or approved the artificial mixtures of asphaltum, such as that from Trinidad; the European cities use for street-pavements asphalt-rock only." Further on Mr. Bell suggests that investments in other kinds of asphaltic materials prevent the Trust from developing the promising asphalt-rock, similar to the Swiss and French rock, found in large deposits in Kentucky and elsewhere in the United States, though in time these deposits, in the hands of good managers, will supply one of the best of pavements. "The composition pavement is sometimes cheaper," he says, "but not as durable as good asphalt-rock pavement." — *Exchange.*

Romantic Recovery of a Bust of Queen Victoria. — A sad little romance lately came to light at Windsor, says the *Ladies' Field.* When the Prince Consort died a bust of him was made, and this was taken everywhere by his widow. At the same time Queen Victoria, desiring to perpetuate the personal appearance of husband and wife at the time of their separation, had a bust made of herself. This was lost sight of by those at Court and there was a tradition at Windsor Castle that, by direction of the Queen, it had been hidden away. The King caused inquiries to be made of an old servant who was on the domestic staff at the time of the Prince Consort's death, and he was able to indicate a place where the bust was walled in. The wall was broken, and the bust — an interesting marble presentment of the Queen's appearance in early middle age — restored to sight.

Glass made Soluble. — A resident of Baltimore has, by means of a chemical solution, succeeded in rendering glass soluble and converted it into a liquid form so that it can be applied to articles and surfaces with a brush, like paint. He believes he has discovered one of the lost arts of enamelling, which was possessed by the Egyptians. The formula used will not be patented, as it is a secret one. It can be applied to wood, iron or any woollen or cotton fabric. A large bathtub was exhibited here which the inventor had painted with liquid glass. The tub glistens like a glass crystal and has a surface as smooth and hard as window-glass. — *Exchange.*

The Guide-books and Rome's Good Name. — In view of the fact that Rome now has good water, and that malaria does not occur within five or six kilometres of the city, a deputation of hotel-keepers recently called on the Minister of the Exterior to ask if means could not be taken to persuade travellers and guide-book makers to drop the antiquated talk about Rome being an unhealthy city to live in. — *Exchange.*

Cost of the Rhode-Island State-house. — The inaugural message of the Governor of Rhode Island shows that the total cost of the State Capitol and grounds has been $3,114,402.10, and reports the expectation of the Commissioners that the entire work will be completed before the end of the present year. — *Exchange.*

NOTES AND CLIPPINGS. 56

THE Chicago ordinance limiting the height of buildings in that city to a maximum of one hundred and thirty feet is to be cancelled, leaving owners free to carry fireproof buildings to any height that they like. The old ordinance could be waived, by special vote of the Board of Aldermen, and the applications for such vote were so numerous that the Aldermen, very sensibly, decided that every one should have the same privileges. The streets of Chicago are so wide that there is much less objection to high buildings there than in the lower part of New York; and, as experience has shown that there is a limit of height, varying with circumstances, to which office-buildings can profitably be carried, it is probable that the matter will adjust itself satisfactorily in course of time. Meanwhile, it seems to us that it is very necessary, before hundreds of millions more are invested in steel-frame buildings, to come to some definite conclusion as to the durability of the metal structure in its envelope of masonry. If paint on the steel favors its destruction, as seems now not improbable, it is time to know it; and if steel vertical members, in the lower stories of a building, endure only a few years, as was believed not long ago, it is time to know that also. There would be no difficulty in whitewashing steel structural members, instead of painting them, as was formerly often done in New York, or in using cast-iron verticals in place of steel, as was common a few years ago, but architects, in order to know what methods to specify, need more accurate information than is at present available. Such information could, perhaps, be best obtained by the Building Departments of cities. Naturally, an architect has very few opportunities of inspecting the skeleton of a building after it has been some years in use, and he certainly cannot pull other people's buildings to pieces for the sake of gaining information for himself; but a Building Department often has occasion to investigate old buildings, for various reasons, and can, if necessary, dissect private property for the public good. The examination needed for this purpose would not be difficult or costly, and its results would be of immense importance.

A CURIOUS case, which dealers in grates and mantels should remember, has been decided by the New York Supreme Court. A Mrs. Archibald hired a house of one Powers, with an agreement that if she continued for a certain time to make regular payments, fixed by the agreement, she should receive a deed of the house. During her occupancy of the house, and without the knowledge of Powers, she contracted with Andrews & Newell, dealers in mantels and gas-grates, to put some of their goods in the house, agreeing to pay for them in monthly instalments. She failed to pay these instalments, and also failed to make her payments to Powers, who, in consequence, took possession of the house. Andrews & Newell then claimed their grates and mantels, under the agreement with Mrs. Archibald. Powers resisted the claim, on the ground that they had been attached to the house, and therefore had become a part of his real-estate. Two courts gave judgment in favor of Andrews & Newell; but the Supreme Court reversed the judgment, holding that if Powers had known of the agreement between Andrews & Newell and Mrs. Archibald, and had assented to it, either explicitly or by implication, he could not retain possession of the grates and mantels; but, as they were put into his house without his knowledge, and were so attached to it, with screws and cement, that they could not be removed without injury to the building, he was entitled to hold them as attached to the realty.

THE Custom house officials of the United States are gaining a reputation for nice distinctions which a corporation lawyer might envy. A few days ago, Senator Foraker, of Ohio, was prudent enough to inquire their opinion in regard to a beautiful altar, of sculptured marble, which is being made in Rome for the convent of the Sisters of Charity at Hamilton, Ohio. Under the law, works of art intended for presentation to an "educational or charitable institution" are admitted free of duty, but Senator Foraker evidently understood the uncertainty whether the Board of Appraisers would consider a convent of Sisters of Charity a charitable institution, or whether they would rate a sculptured angel as a work of art or as a "manufacture not otherwise provided for," and made his investigation in time to prevent, if necessary, the shipment of the altar from Italy. Even his experience was, probably, a little disconcerted at the information that the Custom-house authorities thought it likely that the good sisters would make use of the altar, and that the effect of putting a chalice and a candlestick on it would be to constitute it an object of utility, and not an ornament; and that nothing could be considered, for Custom-house purposes, a work of art, unless intended solely for ornament; and that, therefore, the altar could not, under any circumstances, be admitted without payment of duty. It might be suggested that if the nuns would make oath, supported by a bond filed with the collector of the port, that they would not put any candlesticks or sacramental vessels on their altar, but would use it simply to look at, this ought to bring it back into the category of works of art; but Senator Foraker does not appear to have thought of that, and perhaps the appraisers would be unwilling to trust the good sisters to look at their sculptured marble, for fear that they might, inadvertently, or, perhaps, surreptitiously, put something on it which would instantaneously convert it into a menace to American industry.

THE New York Fine-Arts Federation has been encouraged by the comprehensive scheme prepared by the new Commission for the improvement of Washington to urge upon Mayor Low the propriety of appointing a Commission to draw up a similar scheme for New York, under which improvements, as they are made, shall contribute toward a definite scheme, instead of being taken up separately, and at random. When one thinks of what might have been made of New York, if its unrivalled situation had been taken advantage of at the outset in planning its streets, the immense importance of some such definite scheme in municipal improvement is manifest; and, although what is done cannot easily be changed, it is not too late to plan for the future. Both shores of the Harlem River and Spuyten Duyvil Creek still admit of magnificent terracing, which might make them more attractive as sites for the palaces of the future than even the Riverside Drive; and the great, though unavoidable, defect of the Riverside Drive, that it has no particularly interesting beginning or end, could be provided against on the shores of the Harlem, by making the terraced streets connect esplanades at the terminals of the bridges. These esplanades would be very suitable sites for public buildings, and, with reasonable restrictions as to the architecture of structures fronting on them, nothing in New York would offer a greater artistic opportunity. It is for the purpose of pointing out such opportunities, before they are irretrievably lost, that Commissions, such as the Fine-Arts Federation proposes, are useful; and it is much to be hoped that the municipal authorities will accede to the suggestion.

Entered at the Post-Office at Boston as second-class matter

A REMARKABLE illustration of the way in which great economic ideas, evolved originally by the "kings of finance," or whatever else we may choose to call them, "filter down," as the books say, into the humbler classes of the community, is to be observed just now at the University of the South, somewhere in Tennessee, we believe. At this renowned institution of learning preparations have been made for establishing a laundry, in which the linen of its members may be cleansed. It appears, however, that before the laundry was thought of, the academic linen was washed by the wives and daughters of the mountaineers in the neighborhood, and these hardy citizens, who, as we are told, derive their support from the labor of the female portion of their households, are so far advanced in the knowledge of the new principles of business that they at once proceeded to apply the Standard Oil method to their customers, and notified the authorities of the University that unless the use of the new laundry was immediately discontinued, the University buildings would be burned or torn down over the heads of the inmates, and personal violence would be done to the latter. We are told that two of the most distinguished officers of the University have already "fled," and the application of the new method seems likely to meet with complete success. Now that the ingenious mountaineers have set the example of high finance on a small scale, we may expect to see it widely followed. The occasional lynching of a college professor by his washerwoman, as a penalty for transferring his patronage elsewhere, would have an excellent effect in checking the discontent which people so often feel, not only with their laundresses, but with their butchers and bakers; and as soon as it is generally understood that housekeepers can complain of mouldy beef and last year's eggs only at the risk of their lives, the millennium which the Standard Oil Company, and the coal combination, and the window-glass and tin-plate trusts have so long had all to themselves will begin to "filter down" to the lower strata of the business world.

SOME of the Paris newspapers have been making an outcry about certain cracked stones which appear in the front of the new Opéra Comique. M. Planat, in *La Construction Moderne*, comes to the defence of the architect, and gives, on the authority of an experienced mechanic, an explanation of the trouble. The mechanic, M. Galineau, after observing that the cracks in the stones have existed, in the same condition, for more than a year, says that such fissures, which frequently occur in heavy buildings in Paris, are due to the defective manner of setting stone which is universal in that city. Instead of laying each stone, as is usual in this country, in a bed of mortar prepared to receive it, the Parisian practice is to set the stones on wooden wedges, two to each stone. By driving in the wedges, or drawing them out, the face of the stone is inclined forward or backward, until it is plumb. After several stones have been set in this way, thin cement is poured in at the top of the vertical joints, and makes its way, as best it can, into those and the horizontal joints beneath them, around the wedges. It was formerly usual in Paris to assist in filling the horizontal joints by tucking in additional cement from the front, between the wedges, by means of a long trowel, with serrated edges; but, according to M. Galineau, this process is no longer used. It may be imagined that, on the removal of the wedges, the stones find themselves resting on a very uncertain substratum of cement. Even where the horizontal joints are filled by tucking in mortar from the front, there is no way of compressing it properly, and it forms, in drying, a weak, spongy mass. Where the joint is simply grouted from above, it is a matter of pure chance whether any mortar reaches the horizontal joints, or, if it does, how far it fills them; so that, in this case, the removal of the wedges leaves the blocks supported only at intervals by the irregular course of the grouting under them. Viollet-le-Duc speaks in the strongest terms of reprobation of this method of setting stone, which, as he says, frequently causes the fracture of the blocks through the inequality of the supporting stratum of mortar under them, and M. Galineau makes precisely the same observation.

THE editor of the *Builder* has just made a visit to Baalbek, and gives an extremely interesting description of the work which is being accomplished there by the German Government. Every one knows from photographs the six beautiful Corinthian columns of the Temple of the Sun, which, with their entablature, are all that remain above ground of what was one of the largest temples in the world, and has probably observed, in the same photographs, the enormous stones, some sixty feet in actual length, which form the face of the retaining-wall of the platform on which the temple stands. Since the Germans have taken the ruins in hand, however, a great deal of additional work has been uncovered, and a systematic plan made of the sacred enclosure of Baalbek, and of the buildings surrounding it. From these investigations it appears that the central point of the enclosure was a rock, with a flat top, cut at one side into rude steps. Such rocks are found in various other places in Syria and Palestine, one existing in Jerusalem, and are supposed to have been prehistoric altars, or, at least, altar platforms, while the steps at the side are assumed, without much apparent evidence, to have been made to facilitate the ascent of human victims to the sacrifice. However it may have been with human victims at Baalbek, the flat altar-rock seems to have enjoyed the reputation of great sanctity, for not only was it made, many centuries after the passing away of the prehistoric religion to which it was dedicated, the central point of a group of buildings of a magnificence very disproportionate to the importance of the insignificant town in which it stood, but in later times, when Christianity had become the State religion of the Roman Empire, and the pagan temples were closed by imperial decree, a Christian church was built in the area in front of the Temple of the Sun, in such a position as to bring the ancient altar-rock in the middle of it.

THE discovery of this prehistoric altar is due to the Germans, who, excavating around it, have found, at some distance outside the foundations of the Christian basilica, the remains of a magnificent colonnaded portico, or atrium, some two hundred feet square, entered from a vast hexagonal vestibule, more than a hundred feet in diameter, whose plan suggests a domed covering, which is itself preceded by a portico, or propylea, about one hundred and fifty feet long, with twelve columns, flanked on each side by solid walls. The hexagonal vestibule has an interior colonnade, interrupted by deep niches; and distributed around the great atrium are six exedræ, as if the local philosophers, like those of Athens, discoursed to their disciples in this public place. The altar-stone did not stand in the centre of the atrium, but near the side opposite the entrance, and directly behind it rose the splendid front of the Temple of the Sun. It is evident that the position of the temple was determined by that of the altar-rock, for, in order to place the temple at a suitable distance behind the rock, and with its entrance-door toward the east, which was the rule everywhere with Temples of the Sun, it was necessary to fill the sloping natural surface to a depth, at the western end of the temple, of fifty feet. The huge sixty-foot blocks of stone belong, therefore, to the retaining-wall built to hold the newly-filled earth in place; and, as the German excavations have shown, the same retaining-wall extended around three sides of the temple, enclosing a rectangular terrace, adjoining the atrium at one end, and enough larger than the temple to afford a promenade, some forty feet wide, all around it. The purpose of using the sixty-foot stones, which were indispensable to the construction of a retaining-wall fifty feet high on sloping ground, with such mortar as was known to the Syrians of the Roman period, is thus explained, and the precision with which the Roman engineers estimated pressure and resistance is shown by the fact that their retaining-wall stands firm to this day.

THE city of Paris, whose credit is good, proposes to borrow the sum of sixty million dollars immediately, to carry out certain public improvements "of pressing necessity." Among these improvements is included the erection or completion of three asylums for insane persons, as if insanity were increasing in the city. About fifteen millions are needed for the extension or widening of streets, and a large sum for building new bridges over the Seine, or for widening existing bridges; and it is proposed to complete the Palace of Justice, at a cost of about a million and a half. New sewers will take two millions, and the great highways extending into the country need nearly four millions spent on them within the metropolitan limits. Except a project for a new School of Arts and Manufactures, nothing in the way of interesting architectural work seems to be in contemplation, unless, indeed, the enlargement of the Palace of Justice should include some important new portion.

THE HEIGHT-LIMIT AGAIN UNDER DISCUSSION. — NEW OFFICE-BUILDING UNDERTAKINGS. — THE UNION LEAGUE CLUB-HOUSE. — PROGRESS OF THE POST-OFFICE BUILDING. — OUR LADY OF SORROWS. — THE STADIUM.

THE year of 1902 opens with very great activity in the down-town district. Buildings which, fifteen or twenty years ago, were looked upon as some of the best structures in the city may soon be torn down to make room for larger and higher buildings. Some people are still looking upon the First National Bank Building as one of the best, if not one of the highest, modern office-structures in its vicinity. It seems but a short time ago that we were inspecting its vestibules and halls, and the idea of newness is still associated with it in the minds of many. Now comes the announcement that it may be pulled down to give place to a sixteen-story skyscraper, provided the city ordinance relative to the height of buildings can be modified. This question of the height of buildings here in Chicago is once more being discussed, and at one time recently it looked as if the existing ordinance might become a dead letter. It has been a farce for some time, inasmuch as under the name of "tower" some of the recent buildings have been carried up to almost any height desired. The existing ordinance is useful as providing for the necessity for occasional special permits, always a pleasant matter to the party of the "second part," to borrow a legal expression, and is further supported by those interested in real-estate situated elsewhere than in the very centre of the city. Bringing all the office-buildings within so short a radius of each other, building them so as to hold so many hundreds of people, naturally tends to the greatest congestion of the surrounding streets, and also renders much less valuable even the districts but little removed from the actual centre.

At one time within the last few weeks, it looked as if the recommendations of the Council's Committee on Streets and Alleys would be accepted, granting special permits for building over 132 feet, thus practically annulling the ordinance. On the strength of this there were new schemes springing up on every side for the erection of high office-buildings, and at one time it looked as if the down-town districts might become impassable for the amount of building going on in them. Among others there was a sixteen-story structure to be erected on State Street for Otto Young at a cost of $1,000,000, a fourteen-story annex to the Hartford Building on Madison Street, and still another large building on Monroe and State Streets. Largest of all the building schemes, and one which will doubtless eventually be carried out, is that of erecting an immense office-structure over the half-block bounded by Dearborn, Clark and Monroe Streets, the present site of not only the First National Bank, but the Montauk Building, which only a short time ago was esteemed one of the best and most up-to-date office-buildings in the town, though not carrying so many stories on its foundation as some others. The idea was to tear down the Montauk first and erect that portion for the housing of the tenants disturbed by the demolishing of the rest of the structures. Besides all these plans the managers of the Sherman House are trying to lease their property for ninety-nine years for the purpose of an office-structure. The old Tremont House has seen its last days as a hostelry, and plans have been made to remodel it at a cost of $100,000. The property is owned by the Northwestern University and will be used for college purposes for those departments which are kept in Chicago, rather than at Evanston. In the changing of the building it was first contemplated to include in it an auditorium especially designed for a music-hall. This part of the plan has been abandoned, and it is much to be regretted, as the proposed hall was to have been a model in many respects, Mr. Theodore Thomas having the important matter of acoustics under his supervision as well as some of the minor details which so materially add to the success of such an auditorium.

The scheme for the erection of a new home for the Union League Club is now being actively pushed. The present club-house was built at two different times, the oldest section, however, not being erected more than fifteen years ago. It is one of those Chicago cases of premature old age in a building which in other places would only be considered in the first blush of youth. However, signs of dissolution seem to be upon it, for Chicago is a hard taskmaster when it comes to a question of the buildings which house its thousands. About two years ago a lot of land, 50″ x 100″, just south of the present structure, was purchased, with the thought of eventually adding it to the land now covered by the club-house when the time for a new structure should arrive. It is rumored that the new house will cost in the vicinity of $1,000,000, if an entirely new building is constructed, though some technicality in connection with the land may retard the plan of financiering this somewhat large amount. Several architects have been invited to join in the competition, though it was not opened to all architects who were members of the Club. D. H. Burnham & Company were finally accepted as the architects to do the work, though when it will be done, club-members seem to think, is altogether uncertain. The Club's neighbor over the way, the big white Government Building, is fast putting on the substance of a building. The central walls above the corner one-story structure are now up, with pilasters and carved capitals in place. So, likewise, is the granite about the entrance-ways. The columns with carved capitals, a fine American eagle and several Classic wreaths, are now exposed to the public gaze, and are good pieces of carving. The skeleton dome is rising higher every day, and it will not be long before the exterior stands in its entirety.

A good deal of enthusiasm is evinced here lately in the building of churches. One very large Catholic church, known as Our Lady of Sorrows, has just been dedicated on the West Side. The local papers came out with prints and strong head-lines all attesting to the beauty of this church, "one of the most magnificent in the country. It is built of blue Bedford stone and the style of architecture is *pure Romanesque*. Almost severely plain outside, it is the beauty of the interior that is most impressive." The front façade, which indeed is built of blue Bedford, is of a rather severe Renaissance design, both as to outline and detail, and comes upon one as rather a shock and surprise after having read the description. It most certainly seems a pity that a paper of the standing of this one, in this case the *Record-Herald* (though, as a rule, its architectural descriptions are no worse than those of any other paper) should permit such accounts of recent building to be published. They are, of course, written up by men who know absolutely nothing of their subject, and it certainly seems a mistake that some man, moderately well educated in this branch of art, could not be hired to write such descriptions from time to time as the need for them occurs. If some new stock-yard plant is to be written up, a man knowing something of the business is sent to inspect it, but let some new building be completed, one either deserving high praise or severe censure, and they send out "any old" reporter. He will do to throw together some hackneyed phrases used in art-nomenclature, and the public, having been chiefly fed on such stuff, will never know the difference. But to return to the exterior of Our Lady of Sorrows. As soon as one allows one's eyes to wander from the front to the side façade one sees that brick has become the material used. What is the propriety on a corner lot, where as much, if not more, of the side is seen, of using two different materials is more than the mind of mortal man can perceive, especially in a church, where everything is supposed to stand for truth. Economy is the solving word for such difficult questions, and, no doubt, this would give the correct answer here, but why use stone anywhere, then? Why not brick all around the building? The towers are stone up to a certain point, beyond which, where the eye of man is not supposed to penetrate, they become wood or painted metal. The supporting columns of the entrance are not monolithic, and where they have been cemented are badly discolored and cracked. A very broad band of honeysuckle design finishes the column below the capitals, and gives the somewhat barbaric effect of an armlet, not quite in keeping with the Classic design. The interior of the church has finer points than the exterior, and, if a satisfactory color-scheme is carried out, will present many pleasing features. The ceiling of the nave is one continuous barrel-vault faced with plaster ornamentation very strictly Classic in design. White marble faces the walls for several feet in height, above which everything is plaster. The organ is on each side of the chancel, and when completed may be a feature. The high-altar, the papers tell us, is one of the most beautiful features of the interior, costing $12,000. This may be the ultimate result, but at present only the lower part is marble, while the upper shelves are of wood covered with cambric, and not even an apology for the still higher parts are there, as the monotony of the bare white wall at the back is only broken by a small square window. Owing to the lack of depth of the apse, the vaulting of it is not entirely satisfactory, having the appearance of being unnecessarily compressed. The details are all Classic in character, but are often civic rather than ecclesiastical, as evinced by the fasces over some of the doors. This is unexpected in a Catholic church, where symbolism is apt to be rampant.

Turning from the sacred to the profane, Chicago while building churches is not forgetting her duty as entertainer of the athletes who will be her guests in 1904. The Stadium, where the international Olympic games will be held, is now under discussion, and plans for a huge structure are being talked and thought over. The modern Athenian Stadium had a seating-capacity of between 40,000 and 50,000, and, as Chicago has so much larger country to draw on for an audience, a seating capacity of 75,000 would be none too large to plan for. This seems a goodly number, but when we think that the Colosseum at Rome seated 87,000 and the Circus Maximus over 300,000, an audience of only 75,000 seems quite a little "pinney, pinney poppy show," as we used to say as children. The seats themselves will be covered, and there is some talk of protecting the arena against possible showers by a series of curtains worked by electricity.

PROPOSED NATIONAL ART-GALLERY. — Senator Penrose of Pennsylvania has introduced a bill appropriating $500,000 for a building in Washington to be used as a national art-gallery, "for developing, protecting and perpetuating American art." It is provided that the Secretary of the Interior, the Architect of the Capitol Extension and the Librarian of Congress are to be a committee for the selection of a site for the building, and to have charge of its erection. It is provided that the gallery shall be devoted to works of American artists, and that a commission of "twenty competent connoisseurs" shall be appointed by the President to have charge of the project. — *Exchange.*

DOMESTIC ARCHITECTURE IN ENGLAND DURING THE MIDDLE AGES.[1]—V.

THE FOURTEENTH CENTURY.

THE period of architecture commonly known as the Edwardian period, the Second Pointed, Decorated, or Geometric period of Gothic architecture, extended through the reigns of Edward I, Edward II, Edward III and Richard II—from 1272 to 1399.

By the commencement of the fourteenth century England had made great strides in civilization, the country had become more settled, the laws of the land were consolidated and enforced, and life and property were more secure. In nothing more is this apparent than in the mode of construction adopted in the buildings of the period.

Up to this time secular buildings were marked by simplicity and severity, alike suggesting defence and the aggressive tendencies of the age. The buildings of the Church were, however, removed from the influences and the areas of strife and enjoyed a certain serenity and security, and we find the monasteries, abbeys and churches of this period marked alike by a vigor, delicacy and richness that expressed at once the growth and progress of the arts of peace and of the wealth that enabled their enjoyment.

Beauty and delicacy in art, whether it be in literature, painting, music or architecture, is the living expression of peaceful, prosperous times; thus, we find in the serenity of the Church (the cradle of the arts), that its buildings, paintings and music are among the most magnificent the world has ever produced.

In the early portion of this period flourished the famous institution of chivalry as an outgrowth, or complement, of the Feudal system. This, according to Hallam, consisted in a regular scheme of education, under which the sons of gentlemen, from the age of seven, were brought up in the castle of one of the superior lords, where they were taught the whole discipline of their future profession and imbued with feelings of emulation and a spirit of enthusiasm. From seven to fourteen years of age the boys were styled pages, and at fourteen they were entitled to the distinction of esquire. They were instructed in the manly profession of arms, the art of horsemanship and in exercises of strength and activity. They became accustomed to obedience and courteous demeanor. They attended their masters to the various tournaments and even in battle. Thus, personal valor, emulation, honor, loyalty and courteous magnanimity were inculcated in the formation of the character of the accomplished knight of the period. To this was added the polish of gallantry, deference and devotion to ladies.

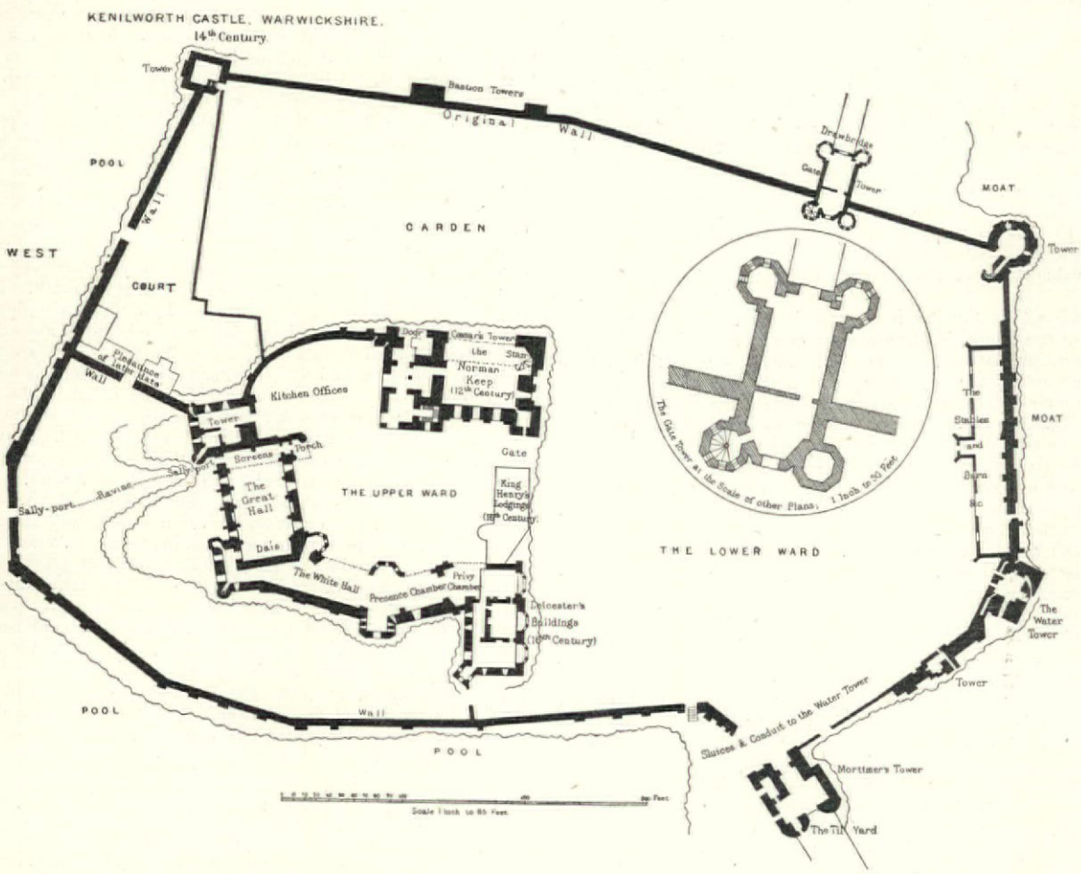
The arts of war, the tournament and the chase formed the chief occupation of the gentlemen of the fourteenth century.

Foreign wars placed England among the foremost nations of Christendom, and the license of plunder and the profits derived from the ransoms paid for the release of captives of high position were sources of attraction to adventurous knights and barons whose numerous trained retinues pressed for active employment.[2]

The spoils of France were found in every castle, and luxury and extravagance increased among all classes.

Great gifts of estate, titles, money and the spoils of the vanquished were bestowed by kings on those who distinguished themselves by their valor and prowess on the battlefield; thus, the career of arms brought not only wealth but founded noble families, established and extended great estates. It is thus, and in these times, that the great family inheritances of England took their rise. But, as there are spendthrifts and improvident men in all ages, many of these estates came at later dates into the hands of the merchant class. The older houses were pulled down, enlarged or beautified, and the former identity of estates, families and their dwellings has disappeared.

It was during this period that Edward III founded the famous Order of the Garter, an order of knighthood consisting of himself, his sons and the most renowned knights of Christendom to the number of forty. The first grand tournament and feast was held on St. George's Day, 1344, in memory of King Arthur, who established the celebrated "Round Table." The King sent his heralds to the courts of France, Burgundy, Hainault, Flanders, Brabant, Germany and Scotland, and the festivities lasted over a fortnight. He also founded and endowed the Chapel of St. George at Windsor, and rebuilt and enlarged the Round Tower and quadrangle, at Windsor Castle.



The language of the country, which, since the Conquest, had been divided, Latin being common among the clergy and learned throughout Christendom, Norman-French the tongue of the nobles and gentry, and English that of the common people, became more consolidated. As an instance of this fusion of tongues we may note that food animals in their live state kept the old English names of ox, sheep, calf, pig, deer, etc., whereas, when dressed, they took the Norman names of beef, mutton, veal, pork, venison, etc. The same influence is found in the established weights and measures. The use of foreign speech was gradually dying out, and English was taught as the standard language in the grammar-schools of the day. The writings of Chaucer in the "*Canterbury Tales*" and Langland in his "*Vision of Piers Plowman*" illustrate alike the language and the manners and customs of the day.

Books, missals, breviaries, psalters and records of all descriptions were at this period written by hand; they were, therefore, comparatively few in number and confined to the monasteries and other centres of learning. The monks were the principal writers of the time, but, as the demand arose, trained writers, or scriveners, appeared, and thus books and records were multiplied.

There was also another class growing up with the increase in

[1] Continued from No. 1361, page 29.

[2] The ransom paid by King John of France in 1360 was three million gold crowns.

commerce; there were merchants amassing princely wealth and consequence. They, too, built themselves dwellings, and their sons were educated to peaceful pursuits, and when we find 12,000 students on the registers of the great school of law at Bologna, similar numbers at Salerno and Paris studying medicine and theology, and many others, we see that the learned professions had made considerable progress at this period of architectural history.

Having, thus, before us the political and social aspect of the country during the Edwardian period, we are better able to understand the people's habits of living, as evidenced in their buildings, and, by noticing the salient features in the architecture of the day, we can picture to ourselves and understand the times during which these buildings were erected.

As wealth accumulated, its possessors naturally sought the comforts, advantages and magnificence that wealth alone could provide. We see this at once in the improvement of their dwellings, their amplification to meet the demands of increased retinues and servants, increased facilities for hospitalities, entertainments and festivities; the separation of the family from their servants; the further retirement and seclusion of the ladies of the household. It is in this direction we find the most marked progress by comparing plans of different dates, as, for instance, Castleton (page 76, vol. LXXII) with Kenilworth. The Saxon thane and early Norman were content with the primitive hall, or common house-place, the one apartment they possessed for cooking, eating, sleeping and dressing indiscriminately, the chamber (or presence-chamber) being first added for the owner's business use during the day, and for the retirement of his family and friends at night. Then came the separate kitchen and its offices amplified around it. During this progressive period we find the first approach made in the refinement and privacy of the family and friends. First, we find its evidence in the Royal lodges where special chambers are set apart for the Queen and her retinue; a little later this is met with in the dwellings of the wealthier nobles, their manor-houses, the granges, and so on downwards.

The hall, or "greet houseplace," became a truly magnificent feature in the dwellings of the wealthy. The merchant-princes emulated the older and noble families in the splendor and extent of their surroundings. The halls of the period were the grandest dwelling-rooms of which we have any record; their magnificent proportions, expansive windows and highly-decorated roofs place them on a par with the monumental works of the Church. Crosby Hall, Eltham Palace and Westminster Hall are familiar examples to every student, and remain almost perfect at the present date.

At one end we find the raised dais, a platform raised two or three steps, on which was placed the high table of state. At the opposite end we find a new feature in a decorative partition of panelled woodwork, usually open, forming a screen to the entrance and to the kitchens and offices. Above this screen was the minstrels' loft, approached by a stairway, usually in the thickness of the wall. The great log fire was still found in the centre of the hall and a louvred turret in the centre of the roof provided the only egress for the smoke. Long tables were ranged at the sides of the hall for retainers and less dignified guests. These were days of wild revelry after the chase, the tournament, or the fray, and after the feast the bulk of the company, both sexes alike, passed the night on the rush-covered floor.

Contiguous to the hall, at the dais end, were the lord's chamber and the lady's chamber, or bower. Gradually, in the manor-houses and the dwellings of the wealthier class, these family chambers amplified in number, forming combined sitting and bed chambers, and the great hall was used more for banquets and great festivities. Private stairs came into use, mostly circular, leading from one floor to another, evolving suites of chambers and also leading to private entrances. The castle-yards became enclosed and were planted with shrubs, forming secluded retreats. Penthurst Place in some measure illustrates this advance.

A chapel, too, is a frequent feature, and a priest's room. The Church kept an ever-watchful eye on the temporal as well as the spiritual welfare of landed proprietors, and the estates of the abbeys and monasteries were frequently increased by bequests and legacies.

The architecture of the period is the Gothic of the previous century, improved, amplified and enriched. The elements of defensive architecture were still demanded by the state of the times, but these essential features were refined in treatment, and decorated, not abandoned, but made less obviously aggressive, or made attractive by their intrinsic beauty and elegance of treatment. Thus, we find the gateway not less massive, but beautified by deeply-recessed mouldings decorated by carvings, the parapets moulded on the embrasures and often panelled on the face.

The keep, or donjon, disappeared entirely; the castle has become the secure and peaceful dwelling, of extent suitable to the rank and affluence of the owner, with its spacious courtyards and expansive lawns, surrounded still with walls of defence, with towers and gateways, within which are sheltered vast barns, granaries and storehouses, with stables and all the necessary out-buildings.

The buttresses, which play such a conspicuous part in the exterior of all mediæval buildings, had during this period more numerous offsets, the weatherings frequently moulded and decorated at the base by panelling and finished at the top by gablets.

The columns of the period were more deeply moulded at the base, and the shafts became clustered, with deep hollows between them. The richly-carved capitals with moulded abaci were very distinctive. The conventional carving of the earlier period had given way to beautiful representations of natural foliage; the leaves and berries of the ivy, maple and oak were the most common, among which birds were frequently introduced. These were deeply undercut in full relief and wonderfully sharp and crisp.

The mouldings, that during the thirteenth century, or Early English period, had become very conspicuously elaborated, now became somewhat simplified; not less beautiful, but more delicate and refined; the dog-tooth decoration, a characteristic of the former period, disappeared entirely, and was replaced by the ball-flower and running sprays of foliage in the hollows.

The work of the sculptor had become more ambitious and as the period progressed we find figures of saints, kings and warriors as isolated works in niches under decorated canopies. They are frequently met with in the more important entrances to churches and monastic buildings and on the walls of castles, manor-houses and granges. The quality of the work is very uniform throughout the buildings of any period.

The windows ceased to be mere loopholes, and gradually widened out and became divided up into numerous lights by moulded mullions, which, as the period advanced, became richly moulded. The heads of the windows, which before had been pierced out of a single slab of stone, were now replaced by geometric figures built up of small stones of the same section as the mullions and known as "bar-tracery," in contradistinction to the plate-tracery of the former period. This treatment of the window-heads as elaborated in the large halls and in ecclesiastical buildings is the most distinctive feature of the period, which, while set out with geometric accuracy, display the utmost grace and beauty in design. There was a marked advance in scientific construction. The walls were better built, the stones were squared and carefully bedded, showing that the forced labor of the unskilled serf, the stability of whose work depended solely upon the ponderous mass of material heaped together, had been replaced by mechanics skilled in the art of construction, who secured better results from the use of less material scientifically disposed.

It is worthy of note, in passing, that the great calamity that swept over Europe about the middle of this period, known as the Plague, or Black Death, had a pronounced influence in the elevation of the laboring-class. This plague is said to have destroyed nearly half the population of England, and, by the consequent scarcity of labor thus created, raised its value and importance, leading up to the ultimate abolition of serfdom and villeinage in England.

In proportion to her population, England is rich in castles, manor-houses and monastic buildings beyond any country in Europe. The Welsh examples of this period form an unrivalled group of themselves, and are infinitely superior in extent and magnificence to any on the Continent of Europe; while such castles as Raglan, Chepstow, Kenilworth, Warwick and Windsor are, for picturesque beauty and elegance of detail, quite unrivalled.

The most celebrated architect of the day was William of Wykeham, who was principal adviser to King Edward III, and who became Chancellor of England. He built the quadrangle east of the keep, and the Round Tower at Windsor; Queensboro' Castle, Kent; established Winchester College and New College, Oxford, later became Bishop of Winchester and rebuilt the nave in its present unrivalled magnificence.

The object of these pages is, if possible, to associate the buildings as we now see them with the times in which they were built, that we may see in them something more than picturesque ruins, and people them with a panorama of the past. The great artist J. W. M. Turner was once painting on the banks of the Thames; a lady approached him and looking over his canvas said, "But do I not see before me the beauties you are painting." He replied, "Don't you wish you could!"

THOMAS C. SORBY.

[To be continued.]

ROME TO-DAY.

FOR the benefit of those who do not have the pleasure of seeing the Boston *Transcript* we make bold to convey bodily from its columns the following account that the Rev. Wolcott Calkins, D. D., gives of the Rome of to-day: —

"Exactly one year after the Kingdom of Italy was constituted by law and proclamation, I entered Rome for the first time. All the way from Milan and Genoa and along the coast to Florence the walls were covered with placards and the people were shouting and getting ready for the anniversary. Possibly this was one reason why I had a bad quarter of an hour in Civita Vecchia. Every article was scrutinized, and at last my Bible was seized, for confiscation if not for the flames. It was only the New Testament, and, fortunately, the Greek text was on every page parallel with the English. I pointed it out to the examiner and assured him that to my certain knowledge the Pope himself cherished an original of that in his Vatican Library as his most valued treasure. With many misgivings he finally permitted me to take the dangerous book into the Sacred City. A dog-cart full of Bibles was the first thing, I believe, that entered the city through the breach at Porta Pia in 1870.

"So I made my exit, March 17, 1862, out of the Kingdom of Italy into the dominion of Pio Nono, escorted from the steamer to train, and received again from train to the city, by French soldiers. In a stay of two months I never lost sight of the blue jacket and red trousers of this contingent of the imperial army. Was this the rude

awakening from Cæsar's dream of Italian unity? Their allies at Magenta and Solferino were now standing with fixed bayonets to stop their approach to the historic capital of the nation. But Bismarck changed all that. In 1866 he admitted the Italians to Venice, and in 1870 to Rome. And now, after nearly forty years from my visit to Papal Rome, and after more than thirty years of its occupation by the kings and by the Parliament of United Italy, I am once more in the Eternal City.

"Italy then meant not much more than a natural paradise, a museum of history, a geographical designation. What is Italy now, and what is it rapidly becoming?

"Rome is not Italy as Paris is France. And yet there is no better way to get started in what I have to tell than to draw a little sketch of what Rome was in 1862, and of what Rome is now. Beyond all question it has lost many of its most lovely and characteristic features. With a pang you search in vain for the magnificent shade-trees of the Villa Ludovisi, and for the Gardens of Sallust. The impressive area of the Colosseum, which you remember as an even ground marked only by the cross in commemoration of the martyrs who suffered there, is half shut off from your approach by vast excavations. You are stopped, as you approach from that side of the Arch of Titus, by a pick-axe brigade, who are tearing up what you used to think was the pavement of the Via Sacra and trying to find another, 10 feet deeper. The smooth level of the Forum, which left only a few exquisite columns and the Arch of Septimius Severus in view, has been succeeded by a vast cavity which needs a lecturer to explain it. As you walk from Saint John Lateran to Santa Croce, you see on your left a long row of uniform and ugly buildings, either vacant or else occupied by Jewish families of average squalor. Then you race across the old city, missing many landmarks and passing thoroughfares that look more like Paris than Rome, and expect to find, at least, the old bridge of St. Angelo intact. No. A new arch on each side has lengthened it out of proportion, and close by it is a horrible bridge of iron. They tell you that they only put it up to serve while the old bridge was impassable, and that they mean to take it down, but you don't half believe that they ever will.

"And where is the glorious view, from the Trastavere, of the grassy banks of the Tiber, and of the old buildings which used to stand thick upon the eastern side, all overgrown with ivy, and all rich in histories of conflict, or intrigue, or adventure? Up and down, the river-banks, as far as you can see, are lined with sloping masonry of uniform stonework; old buildings have been destroyed to make room for the widened river; new bridges, above and below, of French pattern, span the river, and your picturesque old Tiber has become the Seine on a small scale!

"I pity the artists and architects who first encounter these marks of vandalism. But as a man and a brother, I am bound to tell you of some other things, too well remembered, which I see no more. The persistent old beggar, who despite his monstrous deformities used to hobble around the Spanish stairs until you had to give him something, or else step on him, has left no successor. I heard of his retiring from business some years later on an ample fortune. The beggars have nearly all retired from business. I found one cripple on approaching the Vatican, but they tell me that the Vatican is not in the Kingdom of Italy. Of course, the beggars chase you in Naples and all over South Italy, but Rome is almost as free from this pest as Boston.

"There was something immeasurably worse here, in 1862, which has disappeared, or at least has not thrust itself on my observation. In the good order and safety of the streets, Rome is far in advance of Paris and of London. An American lady who has lived here for twenty-five years does not hesitate to go everywhere in the evening without escort, and is never molested. The awful "Roman fever" is also a thing of the past. Recent statistics prove Rome to be the healthiest great city in Europe; the Ghetto, that pestilence-breeding quarter where for centuries, in the ruins of old theatres and porches, the Children of Israel used to drive their plundering trade in old clothes, sham jewels and usury, has been levelled to the ground. An unsightly place with a splashing fountain, quite open to light and air, but destitude of grass and flowers, is left to mark the spot. It is capable of being made a very attractive piazza, of which the adjacent Theatre of Marcellus might be made a grand feature. To the honor of Pio Nono be it said that in 1848, or soon after, the barbarous customs were abolished of locking the Jews in at night and of compelling them to attend a Catholic mass every Sunday and to listen to curses pronounced upon their hated race. But the present Government must have the credit for the final removal of the Ghetto.

"Of course such rapid modern progress as we find in Rome is sure to destroy much that is picturesque, and to substitute more that is commonplace, if not repulsive. The new buildings, public and private, on the Quirinal are wearisome in their sameness of stucco walls. In the entirely new quarter of the city beyond, a worse blunder has been made than on our Back Bay. It was almost a crime to make a rectangular chess-board arrangement of streets in such a city as Boston. Curves and variations in the width of streets ought to have retained in the new the fascinating features of an old city. But we have some relief in the variation in architectural styles. The newest part of Rome has none at all. Sameness and dullness disappoint you everywhere. The effect is even worse across the Tiber, where streets straight as an arrow and too wide for this climate are laid out from the Vatican heights, and lined by uniform barracks.

"But again, as a man and brother, I can see much to admire in all this modern progress. In December, 1870, a few months after Rome had been occupied as the national capital, old Tiber served notice upon its new occupants that they had something else to do than sing pæans of victory. The greatest flood that has been recorded for centuries suddenly inundated the city. The water, which flows normally at a depth of 6½ metres, was swelled by rains in the north, and soon reached a depth of 13½ metres, which always puts the lowest streets under water. This time there was no pause. Higher and higher the floods rose until they reached the unprecedented level of 17¼ metres. The Corso and Ripetta were roaring torrents. The pavement and all the altars of the Pantheon were covered. The whole old city was a lake. The Cloaca Maxima backed up, and drainage was poured back into streets and houses. The millions of damage and the fever-breeding effects of this flood are remembered with a shudder to this day.

"The new Government needed no second warning. The commission summoned Jan. 1, 1871, to take action, made choice of Raffaele Canevari as their engineer. He has made thorough work and has been loyally sustained in his far-reaching plans. The bridge of Saint Angelo at the narrowest place in the river was a dam. To preserve the venerable monument he widened the river, adding the two arches in the old style. To make a smooth, swift current of the enlarged river he lined the banks with masonry. He insisted that all new bridges should make as slight obstructions as possible. Finally, he projected the greatest improvement of all, which has not yet been finished: new main-sewers are to be carried parallel to the river, one on each side, far enough below the city to preclude the refluent current. The mouth of the Cloaca Maxima will soon be closed, and if left at all will only be an unused monument of the republic.

"This colossal work is far from complete. Last winter there was another serious flood, which was much less disastrous and proved that no mistakes have been made in engineering thus far. The new sewers and the elevation of the banks will in time form a perfect protection of the city against this danger, which has been incessant for more than two thousand years.

"There was another immediate necessity confronting the new Government in 1870. It found here a population of 217,000 persons crowded into buildings with only 162,000 habitable rooms. The working people, numbering 57,000, lived in 13,274 rooms, an average of over four persons in a room, and there were slums in which men, women and children, to the number of ten or twelve, spent the night in a single room. The streets were left in a filthy condition, there were nooks and corners, designated by the suggestive name *immondezzai*, where all sorts of garbage might be thrown. The police took little notice of the thriftless Southern habits of the people. There was no board of health worth the name. The malaria of the Campagna shut the city into this narrow compass, which was malarial enough in itself, and Shakespeare's pen could no longer apply to the Rome I saw in 1862 and Cavour saw in 1870: —

"'Now it is Rome, indeed, and room enough.'

"The new Government made an immediate and immense addition to the crowded population. To get room enough was the very first necessity. What wonder that the work was pushed with little regard to landscape or architecture? The vacant heights of the Quirinal were instantly occupied. Former buildings were taken by the right of eminent domain. New structures were hastily erected. The boom resembled what we have seen in Kansas City and other Western cities, and even in Hartford and, still nearer, Boston. New streets were opened and speedily occupied beyond the Quirinal to the Viminal and to the Esquinal. And of course the work was badly done and overdone. New Rome is not artistic, but it is wholesome and roomy.

"There is an amusing confusion in the distribution of public buildings. If you want to 'go to the University' you must be quite sure of what you want and whom you want to see. The University is in the Piazza Sant Eustachio, but when you arrive there with your letter to Professor de Gubernatis, the distinguished author and teacher of Italian literature, you can't get in. You must circumnavigate the building and find the door in the Via Sapienza. You will find Professor Sergi, the anthropologist, in the National Library near the Corso, and Professor Dr. Sante de Sanctis, Professor of Pathology, at his residence, Bocca di Leone, No. 85. When you go to see Michael Angelo's 'Moses' in St. Peter in Vincoli, you will notice on an adjacent hill the ancient monastery of the Canonical Regoliri; it is there that the faculties of the physical sciences and of mathematics have found roomy quarters. The University is everywhere and so is 'the Government.' You think at first that the Quirinal is the new Capitoline Hill. Is not the royal residence there, and next to that the office of the foreign ministry in the former palace of the papal consulata? And farther up the Via Venti Settembre you come to the new building of the War Department, and still farther on to the immense Palace of Finance. But 'the Government' is not all up there. You must go down into the old city to the Palazzo Braschi in the Piazza Navona to find the Ministry of the Interior; across the Corso to the Palazzo Poli, near the Trevi Fountain, to find the Ministry of Agriculture; back again for the temporary quarters of the Ministry of Justice in the Palazzo Firenze; and for the office of the Marine Ministry you turn aside into the old cloister of St Augustine's Church. The rich cluster of cloister buildings between the Via del Seminario and S. Maria sopra Minerva is occupied by the two Ministries of Education and of the Post and Telegraph, and, finally, the General Post-office shares with the Ministry of Public Works the cloister buildings in the Piazza S. Silvestro

in Capite. None of these buildings afford residences for the ministers. They are scattered all over the city, most of them living frugally in some fourth-story apartments. As for the House of Representatives, it has moved often, and is now in a very unsightly building in the Piazza di Monte Citorio. And the Senate in the same building? By no means. You must turn down from the Pantheon towards the river to the Piazza Madama, where a palace of the same name, once the home of Margaret of Parma, and, later, of the Medicis, furnishes a more ornate and more historic place for the Upper House.

"Street changes have been still more extensive and beneficial. We used to start with good courage down from the vicinity of the Piazza di Spagna for the region of the Pantheon; we would soon get bewildered and finally lose ourselves in a labyrinth leading nowhere. Now, the Via Tritone, spacious and on a slight curve, empties the whole of this part of the city into the capacious Piazza Colonna, which opens easily in every direction. The engineers are not satisfied with this. A tunnel is in process of construction which will divert electrics, trams and heavy traffic from this crowded thoroughfare, under the Quirinal and out upon the Via Nazionale. This new boulevard is a splendid avenue from the Piazza di Venezia to the new part of the city, while the grand Corso Vittorio Emanuele opens a wide and entirely new road from near the Capitol through the old city to all the new bridges below the old Ponte Sisto; the heights on the other side of the river have been splendidly improved and crowned with a park, rivalling the old Pincio. Here the equestrian statue of Garibaldi stands, and from this point you have the grandest panorama of the whole city.

"Through these new thoroughfares trolley-cars and trams are running incessantly. For two cents you are swiftly taken from anywhere near the Spanish stairs to the very colonnades to St. Peter's, and for five cents to St. Paul's outside the walls. The system of hacks, strictly regulated by Government, is the best in the world. A clean and roomy carriage with one horse will take you anywhere within the walls for sixteen cents. And if there are four of you it will hardly pay to wait for trolley or omnibus; you will find a cab near-by that will take you by a short cut through the confusing streets to your destination, and the extra four-cent tip, making one lira, will be accepted with thanks.

"There is certainly something twisted in the brain of a writer who grumbles, as Marion Crawford does in his '*Ave Roma*,' about the impiety and the *lèse majesté* of destroying the old city by these improvements. Almost everything that has been destroyed ought to have been destroyed long ago. Light, air, comfort, wealth and immense progress in social and in moral conditions have followed the work of the new Government at every step. There has been sedulous care to guard, or to mark by inscriptions, where removal was unavoidable, historic monuments. The excavations in the Colosseum, Forum and Palatine have made archæological schools, like ours under Professor Norton, and, like the much older and larger German and French schools, a necessity in liberal education. I have not looked in vain for a single book I have needed, in Italian, in French, in German and in English, in the catalogue of the splendid National Library. Rome never had so much to offer the student before."

EXCAVATIONS IN TURKESTAN.

ON an interview with Reuter's representative, Dr. M. A. Stein, who is returning to India after making a preliminary arrangement of the remarkable finds brought to light during his recent expedition in Chinese Turkestan, said that the cursory examination that has so far been possible within the short time available reveals in a striking manner and for the first time many points bearing on the culture and daily life of localities which for many centuries — some for nearly 2,000 years — have been buried under a sea of sand, and whose history has hitherto been practically a blank. Speaking on this point, Dr. Stein said: —

"A full investigation of the sculpture, fresco-painting, objects of industrial art and seals, etc., which were dug out of the temples and dwelling-houses of sand-buried sites will help us to resuscitate the civilization of a region which has played an important part in history as the link between ancient China, India and the Classical West. Now for the first time have been brought to light some aspects of the every-day life, the home industries and arts of the inhabitants of the villages and settlements of Chinese Turkestan which were abandoned in the early centuries after the beginning of the Christian era, and have since been buried under moving sand-dunes. As showing the extent to which the desert has advanced, I may say that some of the settlements excavated are situated fully a hundred miles beyond the edge of the present cultivated area. The great lifeless desert is naturally regarded with much superstition by the people who live in the scanty settlements along the desert edge and the difficulty of carrying sufficient supplies and water has luckily kept the native 'treasure seekers' from visiting and exploiting the more distant and also more ancient ruined sites which have now been systematically explored for the first time under the auspices of the Indian Government. No doubt can be entertained," continued the Doctor, "that the inhabitants of these places were in possession of a culture mainly derived from India, and that they were Buddhists. My excavations go to prove that their culture was highly advanced, and that the art-influences of Greece and Rome were felt even at that great distance from the centres of Classical culture. Khotan is, I should say, about half way between Pekin and Western Europe. Possibly the most striking excavations I made were at a site in the heart of the desert north of Niya, where one settlement was exposed, covering with its scattered dwelling-houses and shrine an area of about six miles by four. Until digging began all that was visible were weird-looking rows of bleached timber pieces projecting in various places like the framework of a wrecked ship from between the sand-dunes. Even with all the interesting work on hand the utter desolation of the place made itself felt most keenly during a prolonged stay, and the uncanny surroundings specially affected my people.

"Of special interest were the refuse-heaps which we unearthed near some ruined houses, once apparently tenanted by village officials — kinds of 'waste-paper' baskets, containing hundreds of documents, beautifully written on wooden tablets, and carefully tied and sealed. Owing to the preservative nature of the sand, many of these were in splendid condition — the ink as black and the seals and string as perfect as if they were only a few weeks old. As these documents are in a known Indian script, their deciphering can be expected to reveal in a fascinating manner many of the details of the ancient village life. But it will be a task requiring years of close study, as in India itself the materials available of this early script have so far been very scanty. At sites less ancient we also found paper documents in Sanskrit, Chinese and also Tibetan manuscripts. In none of the excavations did I find any unknown characters. Round most of the sand-buried houses were brought to light carefully-planned little gardens, with avenues of trees, fenced lanes, orchards, and so forth. It was truly astonishing, on clearing away the sand, to find under the shrivelled hedges heaps of dried leaves, just as they had fallen in ages gone by. The gardens were much the same in character as those still to be found in Turkestan to-day. The trees were mostly poplars and peach, mulberry and apricot trees. There is no evidence that these places were abandoned owing to any sudden catastrophe, but their gradual desertion was evidently due to the impossibility of continued irrigation, causing an advance of the sand.

"While articles of real value were therefore removed by their possessors, we found in the dwelling-places many household implements of small value, such as pitchforks, mouse-traps, boots, chairs, shoemakers' lasts, etc. In the ruined temples we found a sort of unintentional exhibition of the fabrics of these remote ages — for in front of some of the idols were heaps of torn shreds of elaborately-worked silks and other fabrics, which had been deposited as votive offerings. In one temple it was curious to note an instance of where a pilgrim, anxious apparently to propitiate as many deities as possible, had torn into portions a Tibetan manuscript, which he had divided among the various idols. These fragments are now once more united under glass panes. Many colossal statues in stucco were unearthed from the monasteries and temples. One of the latter contained in its cloisters over one hundred statues, all over life size. While as many as possible of these were cleared for the purpose of taking photographs, only a few could be rescued, as when the protecting sand was removed the great stuccos threatened to collapse, owing to their inner wooden work having rotted away. However, interesting portions of them were successfully brought away. As showing how the customs of to-day were in vogue in the past, it may be noted that my laborers at once recognized an ice-pit, which was dug out, by dry leaves, which were apparently used then, as now, to protect the ice from the terrible summer heat."—*London Daily News.*

NOTES AND CLIPPINGS

STONE AND WOOD PAVING IN EDINBURGH. — Rufus Fleming, United States Consul at Edinburgh, Scotland, in a report to the State Department, says: There is a growing demand in this city for the substitution of wood pavements for granite, especially in the principal streets, where the traffic is heavy and noisy. But the municipal authorities, giving attention solely to the question of economy involved, are not disposed to extend the use of wood. Mr. David C. Proudfoot, City Road surveyor, who has had long experience in the making and repairing of streets, informs me that the life of wood-pavement on a main thoroughfare is ten years, while granite of the best quality will last thirty years if relaid once or twice; and as the cost of wood-paving exceeds that of granite, the reason for the municipal preference for stone in street-making is obvious. The wood blocks formerly used for the few streets having this kind of pavement were infused with a creosote preservative — the common, heavy oil from iron-smelting works. A soft-wood block, 7″ x 9″ and 3 inches thick, would take in about two pounds of the oil under a pressure of 120 pounds per square inch. The present wood-pavements are constructed of Australian "jarrah" hard-wood, requiring no creosote, as it contains a natural oil. Blocks 5″ x 9″ and 3 inches thick are laid on a 6-inch concrete bottom with smooth surface, and joined with cement grout or asphalt. This paving costs about $4.10 per square yard. Nine by 4″ x 7″ granite blocks laid on a 6-inch concrete bed and jointed with gravel cost $3.60 per square yard. — *Exchange*.

THE EXODUS OF PAINTINGS TO AMERICA. — A writer for *The London Daily Telegraph* is so alarmed by the number and quality of the paintings by old masters which have gone to the United States or are about to leave Europe, that he urges the formation of a society like the Société des Amis du Louvre to keep in England the fine pictures still in private hands, notably the Bridgewater Gallery, which contains five Titians, among them the "Three Ages of Man," the "Diana and Actæon," and the "Diana and Callisto." The trusts which have prevented the collection at Bridgewater House from dispersal will soon expiré. It contains Rembrandt's "Hannah and the Infant Samuel" and Raphael's "Virgin with the Palm-Branch" and "Bridgewater Madonna." Can we tolerate for a moment, he asks, even the remote possibility that the great Titians and Raphaels might leave England and find a home on the Continent, or, worse still, on the other side of the Atlantic? "If it came to the worst, ought we to suffer this without some serious effort to prevent what should surely be looked upon as a national disaster?" — *N. Y. Times*.

JERRYBUILT. — In a list of words formed out of proper names a correspondent of *Notes and Queries* gives "jerry-build," to which he assigns the familiar derivation from the Brothers Jerry, a Liverpool firm who in the early part of the nineteenth century put up many showy ill-constructed houses in the northern suburbs of that city. But this etymology has been disputed, and now the *Builder* tries to knock it finally on the head. In this it has the negative support of the "*New English Dictionary*." Dr. Murray says that the origin of the term has not been ascertained. His earliest quotation for it dates only from 1869, and he states that the Liverpool story has been inquired into, but has not been confirmed. A correspondent points out that the term is probably no more than a late manifestation of the old contempt thrown into "Jerry," as an abbreviation of Jeremiah at the time when the Puritans were giving Old Testament names to their children. "Gerrymander" has quite another origin, being taken from the name of Elbridge Gerry, a wire-pulling American politician; but it may be noted that the alleged operations of the Brothers Jerry at Liverpool are assigned to the "early part of the nineteenth century." It was about 1810 that "gerrymander" became current, and it may well be that this new phrase, acting in conjunction with the Jeremiah tradition, suggested "jerrybuilt." From several correspondents we receive evidence of quite another derivation of the "jerry-builder." Among bricklayers, it is said, the walls which were not firm until they were papered were formerly called "Jericho walls," in obvious allusion to the walls which fell down flat when the priests blew with the trumpets. — *London Chronicle*.

THE CHICAGO-RIVER TUNNELS. — Shall Chicago abandon its position as a lake port and become commercially an inland city? This is the question which Secretary Root, in his answer to the request that the Federal Government aid the city in widening and improving the Chicago River, has practically put to the citizens of Chicago. The tunnels now used by the traction-companies are the key to the problem. Until they are removed or lowered vessels drawing over 16 feet of water will be unable to enter this port, which means practically that all important lake navigation will in the future be barred from the Chicago River. In approving the plans of the Drainage Board for widening the river to 200 feet Secretary Root has emphasized the inability of the Federal Government to enter upon any comprehensive plans of river improvement until the tunnels are lowered and the centre-pier bridges removed. The Drainage Board is ready to spend $11,000,000 for the widening of the river and the acquisition of condemned property along the lake-front. The deepening of the river, however, is in the interest of lake commerce, and the city is again assured that not a dollar can be expended for this purpose until the obstructions for which the city is responsible are removed. Even the appropriation of $500,000 included in the River and Harbor Bill for the building of two turning-basins in the Chicago River will not be available until the city has lowered the tunnels. Thus far no definite steps toward compelling the traction-companies to remove or lower the tunnels have been taken, and unless something is done speedily it is reasonable to predict that Chicago's prestige as a lake port will ere long become a matter of history. — *N. Y. Tribune*.

TELEPHONE-POLES FOR EGYPT. — The Telephone Company of Egypt, Limited, operating a large telephone system in Egypt, has experienced great difficulty in securing a suitable pole. The climate of the country is so hot and dry that good timber to use for a pole line for the transmission of an electric current does not grow, and timber imported from other countries dry-rots and becomes useless in a very short time. A certain pole imported from Sweden proved to be the most valuable so far, but its greatest life was not over four years. The Company began negotiations, therefore, with cedar-pole firms in the United States, with the result that arrangements have just been completed with W. C. Sterling & Son, of Monroe, Mich., wholesale producers of cedar poles, ties and posts, for the shipment of 1,500 poles of the white-cedar variety, Michigan-grown, to Alexandria and Cairo, Egypt. Correspondence opened between the two firms last June, but owing to the great distance and slow transportation of mail-matter, arrangements were not completed until last week, and the shipment of the material will begin at once. — *Electrical World and Engineer*.

DUST AND CONSUMPTION. — That dust is a cause of consumption is clearly shown in the statistics of the patients treated at the sixty institutions of the German Empire for the cure of tuberculosis. In 1,095 cases, or more than one-half of the 2,161 persons under consideration, the origin of the disease was alleged to be due to the continuous inhalation of dust involved by their employment, as follows: 431 cases from the effect of "dust" without more exact designation; 182 cases from the effect of metal-dust; 129 cases from the effect of stone, coal or glass dust; 116 cases from the effect of wood-dust; 111 cases from the effect of wool-dust, and 126 cases from the effect of various kinds of dust. These facts suggest to hygienists and inventors the necessity of devising dust-consumers and dust-preventers for factories, workshops, etc. This is a fact that legislators should bear in mind. — *American Medicine*.

NATURE OF LIGHTNING. — In an article recently printed in the *Physikalische Zeitschrift*, K. R. Koch says that he has found that lightning-conductors whose connections have become imperfect through rusting or otherwise act, nevertheless, in an efficient manner in case of a thunder-storm. This is, in his opinion, due to the oscillating character of lightning-discharges. Electro-magnetic waves are produced, which act upon the imperfect connections as upon a coherer, restoring their conductivity for a more or less long period. Lightning has hitherto been considered a continuous discharge, which often becomes apparently oscillatory by quick repetition. The author employs a rapidly revolving camera in order to test this question, but does not arrive at any definite conclusion, as the flashes photographed were all too distant. — *Exchange*.

TENANT'S RIGHT TO REMOVE FIXTURES. — In the submission to the Second Appellate Division of a controversy between Frederick B. Van Vleck, as trustee of Joseph L. Quesenbury, a bankrupt, and Alexander M. White, the question was as to the ownership of a boiler and engine situated on premises owned by the defendant. Quesenbury had been a tenant of Mr. White, having placed the boiler and engine on the premises when he first took possession. Justice Sewell, for the Court, holds that the right of a tenant to remove trade fixtures, placed by him upon the leased premises, must be exercised before the expiration of the term, or before he gives up possession. Assuming, says Justice Sewell, that an unexercised right to remove trade fixtures passes to a trustee of the estate of the tenant appointed in bankruptcy proceedings the day after the issuing of a warrant for the removal of the tenant for non-payment of rent, the trustee loses such right by accepting from the landlord a new lease of the property, "together with the buildings thereon and the appurtenances," not containing any reservation of the right to remove the fixtures. — *N. Y. Times*.

NOTES AND CLIPPINGS. 63

THE New York Chapter of the American Institute of Architects, with the support of the Fine-Arts Federation, has taken the initiative in a step of great importance to the public, and to the profession, in suggesting the draft of a bill, which has been introduced in the New York Legislature, providing that the Mayor of New York shall, before June 1, 1902, select, from a list of one hundred candidates presented by the Fine-Arts Federation, fifty architects, who shall be listed as "Eligible Architects for Municipal Work," and that architectural work for the city of New York, or for any of its departments, shall thereafter be confided only to architects whose names appear on the list. Provision is made for increasing the number, by yearly selection, until the list contains one hundred names; after this, vacancies are filled, in a similar way, only as they occur. The Fine-Arts Federation is at liberty to propose candidates not resident in New York, and the Mayor may select such candidates. The bill, as introduced, is an excellent one, showing every indication of the utmost fairness of intention on the part of those concerned in drawing it, and it has received deserved commendation and support from a very large number of architects, both members and non-members of the professional societies in New York.

AS to the effect of such a measure, if it should be passed, as seems quite probable, it need hardly be said that the assurance that it gives that public building work will be placed in proper hands is of the greatest value. New York has suffered less, perhaps, than many other cities from the ignorance and incompetence of those whom political influence or favoritism has put in charge of important building operations; but it needs to be secure in this respect, and the course of the authorities in recent years has not been such as to encourage the belief that professional reputation and skill constituted the sole claim to their favor. To put it out of the power of a new administration to reward political services by giving architectural work to incompetent men, or to utilize a dishonest architect as a means of plundering the public treasury for the benefit of politicians, will be a great gain for the city; and this the new bill would do effectually. Few people outside the profession know how great are the opportunities offered to architects for robbing, or helping other people to rob, the owner of a new building, or how strong and persistent is the pressure on the architect of a public building to connive, or, at least, to wink at, overcharges, needless extras, and violations of the contract, in favor of some one influential in politics. Many a young architect, who had fairly won a public commission, has been ignominiously discharged, without explanation, or forced out of his position by deliberate insult and annoyance, to make room for one more ready to join in schemes for diverting the public money into the pockets of politicians; and a law which will exclude from employment on public building work every one not trained in the principles of professional integrity, as well as of professional science, is a most prudent measure.

THE profession, also, has something to gain by a law of the sort proposed, not so much in the way of employment as in the encouragement which it will give to the younger men. In France, the appointment as "architecte du gouvernement" means almost precisely what selection for the eligible list would in New York under the Davis bill; that is, simply, qualification for public professional work. The "architecte du gouvernement" very often passes his whole life without a public commission, but the fact that he has been selected as qualified to carry one out, if occasion should offer, is regarded as a high professional honor. The architect on whom it has been bestowed is careful to make the fact known on all occasions, by adding the title to his name, and it is, naturally, of great advantage in private practice. The man whose name figures on the New York eligible list, particularly if he is young, should find similar advantage in the circumstance; and the chance of winning a place on a list of one hundred is sufficiently good to act as a great encouragement to all architects practising in the city. Some such encouragement is more needed than anything else by the profession in this country. The younger practitioners, who see the award of the most important public commissions secured by bribing servants, or in other equally discreditable ways, become cynical, and, instead of doing their best, fall into the habit of doing what they think most likely to please the unskilled, even if honest, judges who control the decision. For such men a test in which the judges are the most accomplished men in their own profession is a pleasant, as well as wholesome, tonic, and such a test the Davis law provides; for it is very certain that no architect who, in his competition drawings, suspends towers in the air over the middle of large rooms, or who adorns his buildings with Corinthian pilasters without bases, or gives other evidences of imperfect professional attainment, or doubtful professional sincerity, or who has been detected in violations of the code of professional ethics, will ever be presented as a candidate by the Fine-Arts Federation, the ablest and least prejudiced professional tribunal in New York. To receive the suffrages of such a tribunal, or of the similar ones which would be likely in other cities to follow the establishment of one in New York, would do more to encourage a young architect, and strengthen him in his artistic development, than a dozen commissions secured from friends, or from non-expert judges; and the artistic future of this country needs nothing so much as this sort of recognized and skilled criticism.

THE Westminster Chambers matter has come up again in the Massachusetts Legislature in a new form, the city of Boston having petitioned for a change of the law, permitting buildings on the east side of Copley Square, which would include Westminster Chambers, to be "completed, rebuilt or altered" to a height of one hundred feet, instead of ninety feet, as the law stands at present. The object of the petition is evidently to save the city money, for, the Supreme Court having decided that the law establishing the ninety-foot limit was constitutional, the portion of it requiring the city of Boston to pay all damages consequent upon the restriction is sustained with the rest, and the city finds that its bill will be considerably smaller if the Westminster Chambers is permitted to remain as it is, at a height of about ninety-six feet. Now that the Museum of Fine-Arts, which alone, out of all the petitioners for the original restriction, had a tangible reason for its action, is to be removed, there is no one left who will be in the slightest degree injured by letting the Westminster Chambers stay as it is, and the taxpayers of the city, of whom not one in a thousand takes even a sentimental interest in the matter, have a claim to be considered. The newspapers have begun their usual outcry about "defying the law," and so on; but the Legislature which passed the original law has a perfect right to pass a modified one, if it sees fit, and a statute for the relief of the taxpayers of Boston is a very different affair from one intended to make a special exception to a law applying to a considerable number of estates. We have always thought the original law arbitrary and oppressive, and, while that would not justify any one in defying it, a great many people will think that, after the reason for the original law had been removed, a small retrograde movement in the direction of equal rights for all citizens might not be amiss, independent of any

Entered at the Post-Office at Boston as second-class matter

consideration for the taxpayers' pockets. One of the Boston newspapers makes a rather unfortunate comparison of the Westminster Chambers with the Algonquin Club, the front wall of which originally projected beyond the street line, and was, by order of a court, taken down and rebuilt. In the case of the Algonquin Club, however, the restrictions were clearly fixed in the deed of the land, and it was the neighboring owners who objected, with good reason, to the construction of the club-house on territory in which they had rights. This was quite a different matter, and it was as much for the interest of all the citizens to see that no owner was allowed to encroach on the property of his neighbors or of the public as it is now to see that no one is selected for special oppression without good reason, and that, if the reasons which make oppression necessary are removed, the oppression shall, so far as possible, cease.

NOTWITHSTANDING M. Santos-Dumont's occasional misfortunes, his attempts at navigating the air form the most interesting and important events of the day, for, in his fragile craft, the daring inventor carries the fate of empires. Starting from Nice the other day, while waiting for a favorable wind for a trip to Corsica, he sailed over the water to Cape Martin, and then turned and came back, performing "graceful evolutions" with his balloon. Cape Martin is only about two miles from the Italian frontier at Vintimiglia. If, then, France and Italy had been at war, as they have been on the point of being several times within the last five or six years, it would have been easy for him to sail for a few moments farther eastward, and, instead of amusing the ladies on the beach at Mentone, to perform his "graceful evolutions" over the Italian fortifications at Vintimiglia, leaving them, with the aid of a few packages of explosive gelatine, a mass of ruins, and the way clear for the march of an invading army. Moreover, Cape Martin is in plain sight of the great city of Genoa, and the naval station of Spezia, and a few more "graceful evolutions" would be quite sufficient to destroy the docks of Spezia, and the vessels under construction there, and to render the fortifications of Genoa useless.

ALL these things are obviously already within the power of Santos-Dumont and his balloon, and it cannot be doubted that, before many months have passed, machines will be built capable of taking much longer and swifter flights, and carrying greater burdens, than are suited to his modest craft. When this result has once been attained, the political equilibrium of the world must inevitably begin to rearrange itself. It need hardly be observed that the system of civilization by extermination will be the first to fall before the new force. When science has put it within the power of an oppressed or defeated people, however weak in numbers, to build or buy, at a hundredth part of the cost of a battle-ship, a machine which will travel over sea or land, more swiftly than any steamer or railroad train; which can, in an instant, destroy the most powerful naval vessels, either at sea or in port, blow up railway bridges and viaducts, and the ammunition and commissary trains of armies on the march, and, flying over the heads of the armies, can burn and destroy the enemy's cities, the coercion of weak nations by the strong ones must cease. The stronger the oppressor, the greater and richer will be the cities which lie at the mercy of the avenger, and the advantage, in such a contest, will be on the side of the poor community, which has no cities, ships or armies to lose, but possesses the means of destroying those of its enemies. It is not necessary that a Santos-Dumont should be found to sail in every air-ship. When once the secret of directing the flight of a balloon is known, its capacity as an engine of destruction can be utilized without the employment of a pilot. Supposing, for example, the people of the Low Countries to wish to make a "demonstration" in behalf of their brethren in South Africa, it would be by no means difficult, even in the present state of knowledge, to send a swarm of balloons, driven by compressed-air motors, or something of the kind, over the hundred miles or so separating the Belgian coast from London; and, with fuses timed with even moderate precision, fire and destruction could be scattered through the metropolitan district. It is true that such an attempt would be immediately followed by the appearance of a British fleet off the Belgian coast, but, with a few "graceful evolutions" of a Santos-Dumont, the English vessels could be sent to the bottom before they reached their destination. We have no wish to suggest, still less to encourage, the application of science to violence, but prudence in anticipating events is the best means of avoiding or mitigating them, and the peace of nations, and the security of their citizens, will be promoted by the clearest possible understanding of the offensive resources which the near future will afford, and which will render navies useless, make foreign expeditions impracticable, and transfer the devastation of war to the centres of population.

IN a more peaceful field, the advent of the navigable balloon will have important and extended consequences. Supposing M. Santos-Dumont, instead of a person of scrupulous integrity, to be intent upon dishonest gains, it is difficult to see how he could have been prevented, after flying from Nice to Mentone, from flying a few miles farther, and landing, at some point across the Italian frontier, such portable articles as he might wish to introduce into Italy without paying duty on them; or, to suppose a case nearer home, if a rival aëronaut were to start at night from some point in Northern Mexico, and land a hundred thousand dollars' worth of jewelry somewhere in Texas, where an agent of New York or Chicago jewellers was waiting to receive it, no possible vigilance of Custom-house officials could prevent him. The duty on jewelry brought into the United States is sixty per cent, so that the profit on each trip would be sixty thousand dollars, and it would be easy to make a trip every night. As in the other case, we are very far from advising any one to imperil his soul in such adventures, but it can do no harm to point out that, if persons deaf to the voice of wisdom should indulge in them, the consequence would be the speedy bankruptcy of all, or nearly all, the jewellers in the United States not concerned in the conspiracy, for the obvious reason that the contraband dealers, having a sixty-per-cent advantage over their competitors, would soon have all the trade. The same system would, undoubtedly, be utilized for the importation of other goods, having great value in a small compass, and burdened with heavy duties, and it would not be surprising to see some of the most highly protected industries brought, by the introduction of the navigable balloon, to the position of earnest advocates of a change in the tariff, as the only means of saving them from ruin.

SOME one, who has been inspecting the list of delinquent taxes about Chicago, finds in it evidence of the collapse of the great speculation of 1893 in lots in the "extension of Jackson Park, Chicago," as it was called. It will be remembered that Jackson Park borders on Lake Michigan, and about three million dollars were paid to the promoters of the scheme in return for deeds of lots from six inches to three feet under water. These worthless lots sold, in some instances, for three thousand dollars each. Now, the owners do not care to pay the very trifling tax upon them, to keep them from being sold by the sheriff. The moral of this tale is that people who propose to buy land as a speculation will do well to see the land before they commit themselves; and, in the case of Chicago speculations, even this is not always sufficient. Years ago, when Chicago was growing rapidly, the real-estate operators were said to have a way of buying up a large tract, laying out and grading streets, setting lamp-posts and so on, and then advertising a grand excursion and auction sale for a certain day. On the appointed day, the excursionists found the place swarming with workmen, new houses going up on every side, bricks, mortar and lumber encumbering the streets, and the air full of the cheerful sounds of trowel and hammer. The auction then began, amid great enthusiasm; large sums were bid for choice of lots, and multitudes of the visitors went home feeling that they had secured a fortune by a successful bid. Before the last excursion train was out of sight, the sound of hammer and trowel had ceased; the workmen were packing up their tools, carts were removing the bricks and lumber, and, by nightfall, the place had reverted to solitude.

OF necessity the exigencies of rapid serial publication compel editors to depend on certain routine systems which are supposed to be automatic in their working; but now and then these routine operations break down, as any system in which the personal equation enters is liable to do. Some of our readers possibly detected that the illustration of the Post-office at Kansas City, Kans., published in our last issue had already made its appearance in our issue for November 10, 1900. The accidental replacing of a used negative among those not used is probably responsible for the republication. Fortunately, Mr. Taylor's designs are so satisfactory, a second appearance of one of them can hardly be considered a grave misfortune.

THE CROSS IN HISTORY AND ART.[1]

THE simple Latin cross, free from floriation or ornament, is known as the cross of suffering or passion. It represents the actual gibbet-altar upon which the atonement was offered. The barbarous execution by crucifixion, of which traces are to be found from a very remote period, was carried into effect in two forms — viz, when the sufferer was left to perish bound to a tree or an upright stake, sometimes after being impaled; and when by nails driven through his hands and feet, his limbs also sometimes further secured by cords, the sufferer was fixed with outstretched arms to a cross having a horizontal bar as well as a vertical stake.

The form of this instrument of punishment inspired a deep and unmitigated horror on the part of the Romans. Cicero, who lived before the Christian era, says that "the very name of the cross was banished from the thoughts, eyes, and ears of a Roman citizen," and several generations elapsed ere the old ideas connected with the "arbor infelix" gave way before its new meaning, so that it was not till the middle of the fifth century, more than a hundred years after the cessation of death by crucifixion, that the pure form of the cross emerged to sight. . . .

THE PUNISHMENT OF THE CROSS.

This form of punishment was in ancient times a very ordinary one, and of far wider extent than is generally known. It was common among the Scythians, the Greeks, the Carthaginians, the Germans, and the Romans, who, however, principally applied it to their slaves, and rarely crucified free men unless they were robbers or assassins.

Alexander the Great, after taking the city of Tyre, caused 2,000 inhabitants to be crucified. Flavius Josephus relates, in his "*Antiquities of the Jews*," that Alexander, the King of the Jews, on the capture of the town of Betoma, ordered 800 of the inhabitants to suffer the death of the cross, and their wives and children to be massacred before their eyes whilst they were still alive. Augustus, after the Sicilian War, crucified 6,000 slaves who had not been claimed by their masters. Tiberius crucified the priests of Isis, and destroyed their temple. Titus, during the siege of Jerusalem, crucified all those unfortunates who, to the number of five or six hundred daily, fled from the city to escape the famine, and so numerous were these executions that crosses were wanting, and the land all about seemed like a hideous forest. . . .

THE CROSS IN ART.

Crosses exhibiting an endless variety of form, proportion, and adornment surmounted the loftiest architectural features of cathedrals and churches, while here and there upon the masonry they attested the consecration to Christian worship of the buildings which bore them. With the triumph of Christianity, the cross was recognized as a symbol of the highest dignity and honor. It was made of the most precious materials, enriched with the most costly gems, and adorned with most exquisite art. The cross became the proudest ensign upon royal diadems, and it gave both their form and their name to the noblest insignia of knightly rank. The cross crowned the sceptres of princes, and warriors of renown were proud to see the cross as well in the hilts of the swords as in the banners under which they fought. In private life also the cross was held in corresponding estimation, and, accordingly, the most beautiful and most highly-prized personal ornaments appeared in some cruciform type. In this connection it may also be mentioned that Justin Martyr said, "The sign of the cross is impressed upon the whole of human nature. There is hardly a handicraftsman also but uses the figure of it among the implements of his industry."

The mediæval artists delighted in designing the cross under various conditions of both form and decoration. They wrought leaves and flowers into cruciform figures, and adorned their crosses with foliage in every degree of richness. They made the cross both simple and compound; they introduced it in combination with other figures and devices; and they composed it from figures and devices, each one of them having some definite motive or significance of its own. . . .

CROSSED AND CRUCIFORM STANDARD MEMORIALS.

Among the remains of early monumental art preserved in Scotland, none, it is believed, can be accounted more interesting and worthy of thoughtful inspection than those curiously pictured pillars described by Gordon, Cordiner, and other topographers of the eighteenth century. Of their age and purpose nothing seems to be known more precisely than that they were probably set up at a remote time, either as wayside incentives of devotion — to commemorate a military leader slain in battle — the battle itself — or, as some are disposed to think, to mark the boundaries of jurisdictions and feudal territories.

In local parlance they are called Danish stones, in accordance with tradition, which has always connected them with the battles fought with the Northmen in the early part of the eleventh century. But, however much they may be historically associated with Danish transactions, it does not follow that the Danes themselves had anything to do with their erection, for it is not to be supposed that they would be at the trouble and expense of erecting such artificial monuments of their rapine. Besides, these stones have generally crosses, while the Danes at that period were not Christians. It is, therefore, concluded that these remains belong to the Picts, the inhabitants of the country. In another passage regarding these pillars Pinkerton believes that some of them belong to the period between 843 and 1056; and again, with reference to the sculpturings upon them, thinks "it may be also reasonable to infer that the centaurs, elephants, and some other representations on these singular monuments, may have passed from the Roman mason left in Britain, after the departure of the military force, to their native apprentices, and thus having descended with the craft, as traditional decorations without meaning, as the skulls of bulls used in ancient sacrifices continue to mark certain parts of modern architecture."

These pillars, which are confined almost altogether to the northern and north-eastern counties, consist of a parallelogrammic pillar of one stone, varying from about 5 feet to 22 feet in height, from 18 inches to nearly 6 feet in width, and from 3 inches to 16 inches in thickness. In most instances a Latin cross, with short arms hollowed out at the angles of intersection into half, three-quarter, or entire circles, trefoils, or rectangular notches, occupies, more or less in relief, one, not unfrequently both, the superior faces of the pillars. Often the arms of the cross are free; as frequently, perhaps, they are surrounded by a circular fillet, or wheel, or by a cincture of slightly elliptical shape. In all instances the cross, which generally occupies the whole plane of the pillar, is ornamented variously with bosses, pellets, figures of men and animals, etc.

While on the subject of carved and cruciform pillars, a few straggling specimens of miscellaneous character may be mentioned, which, although in main part comparatively modern, may in some instances be coeval with the oldest of the kinds above referred to. Of these, the nearest to the Norman type are a curious cruciform specimen in the islet of Inishail, Loch Awe; one of slab form, with cross, etc., beautifully situated over a well at Kilmory-Oab, in Knapdale; and another, overspread with the cross, braided work, etc., at Corsewall, on Loch Ryan, Galloway.

In the village of Dull, Perthshire, and in its immediate vicinity, are several plain, ponderous cruciform pillars, evidently the production of a rude time; and of the same sort are some heavy specimens standing on the low, grassy Eilean Finan, in Loch Sheil, in the highland districts of Moydart and Sunart. The pillar at Eccles, Berwickshire, incised with some coarsely-executed figures, and ending in a solid disc quartered on both faces by a plain cross; and the Merkland Cross, near Kilpatrick-Fleming, Dumfriesshire, nearly 10 feet in height, are quite distinct types, and the latter of no great antiquity.

The well-known Ruthwell pillar, which by some is supposed to be of early Saxon date, is about 18 feet in height, and so far as shape is concerned belongs to the class of tapering cruciform pillars with the limbs cusped.

MONUMENTAL CROSSES.

The crosses upon stone coffin-lids or sepulchral-slabs, which in England first appear at the close of the eleventh century, and from that period gradually became general, were executed either in low relief or by incised lines, while in some instances the two methods of treatment were combined. Occasionally repeated in the same example, the cross sign, exhibiting a truly wonderful variety of design, at first appears alone, the shaft, or stem, almost always considerably elongated, and often enriched with sprouting foliage or some other ornamentation. When the elongated shaft of a cross or slab rises from two or more steps at its base it is said to be a Calvary cross, and after a while a brief inscription was added. Then the further addition appears to have been introduced of some device or figure which symbolized the profession, occupation, rank, or office of the person commemorated — such as a pastoral staff for a prelate, a chalice for a priest, a sword for a knight, a trumpet for a trumpeter, a bell for a bell-founder, a hammer and pincers with a sword for an armorer, a horseshoe and hammer for a smith, etc. In a few instances a knightly sword placed erect in the centre of a slab either acts as the shaft of a cross, or with its cruciform guard to the hilt, the figure of the weapon itself becomes the cross symbol. There are also occasionally found early monumental stones, upon which both a cross and the head or bust and the feet of a human figure are so treated as to form a single composition. Kneeling figures, again, are sometimes introduced either at the foot of a monumental cross or on each side of the shaft of such a cross, and full-length figures in other examples appear placed within the expanded floriated heads of monumental crosses. . . .

QUEEN ELEANOR'S CROSSES.

The marriage of Eleanor, daughter of Ferdinand III, King of Castile, with Prince Edward of England, when fifteen years old, took place in May, 1254, at the castle in Burgos, Spain, and it was on Sunday, August 19, 1274, that Edward I and his Queen Eleanor were crowned in Westminster Abbey. During almost thirty-six years she was the constant companion of her husband on his perilous journeys, while the issue of the marriage was seventeen children — five sons and twelve daughters. Holinshed, in his "*Chronicles*" under date 1291, records: "In the nineteenth yeare of King Edward, Queen Eleanor, King Edward's wife, died upon Saint Andrew's Even at Hirdebie, or Hirdlie, neere to Lincoln, the King being as then on his waie towards the borders of Scotland; but having now lost the jewell which he most esteemed he returned towards London to accompanie the corps unto Westminster, where it was buried in St. Edward's Chapell, at the feet of King Henry III."

[1] Extracts from a paper in the *Illustrated Carpenter and Builder*.

In the solemn procession with which the embalmed corpse was slowly brought to Westminster the King himself was the principal mourner, and that passengers might be reminded to pray for her soul he caused a stately cross to be erected to her memory at every place upon the road where her remains rested — namely, Lincoln, Grantham, Stamford, Geddington, Northampton, Stony Stratford, Woburn, Dunstable, St. Albans, Waltham, Cheapside, and Charing. Dean Stanley, in his "*Memorials of Westminster Abbey*," says: "The crosses erected at all the halting-places of the remains of her kinsman, St. Louis, from Mont Cenis to St. Denis, seemed to have furnished the model of the twelve memorial crosses which marked the passage of the Queen of good memory from Lincoln to Charing."

Holinshed says: —

"She was a godly and modest Princesse, full of pitie, and one that showed much favour to the English nation, readie to relieve everie man's grief that sustained wrong, and to make them friends that were at discord so far as in her laie. In everie town and place where the corps rested by the waie the King caused a cross of cunning workmanship to be erected in remembrance of her, and in the same was a picture of her engraven. Two of the like crosses were set up at London, one at Charing and the other in West Cheap."

At Geddington the cross still exists in the middle of the town where the three principal streets centre. The Rev. C. H. Hartshorne, in "*Historical Memorials of Northampton*," says that the three figures of Eleanor upon this monument exhibit a similar cast of countenance to the others. There exist the same elegance of outline and skilful arrangement of drapery, thus evidently showing that all of them, with the four figures round the cross at Northampton, are copied from the same original. With regard to this cross, a writer says: "The cross at Geddington fares remarkably well. I have never heard of its being defaced, nor have I seen any signs of ill-treatment. The weather, of course, affects it to some extent."

The cross at Northampton, which stands on an eminence about three-quarters of a mile south of the town of Northampton, was the work of John de Bello, or De la Bataille, who also erected the crosses at Stony Stratford, Woburn, Dunstable, and St. Albans, between the years 1291 and 1294. About the base of this cross is a flight of steps. The shaft of this cross is divided into three stages. The first is octagonal, 14 feet in height, and each face of the octagon measures 4 feet. On the south and east sides are the arms of Ponthieu in Picardy, and in another escutcheon those of the kingdom of Castile and Leon. The shaft of the second stage, or story, is of the same shape as the first one, but only 12 feet high. The upper shaft is square, each side facing one of the cardinal points of the compass. Its height is only 8 feet.

Waltham Cross stands on the side of the high-road, where the Queen's body rested. Its erection was begun by command of the King, under the superintendence of Nicholas Dymenge de Reyns, in 1291. Three other persons appear to have had some share in the work — viz., Roger de Crundale, Alexander le Imaginator, and Robert de Corf. The whole cost was £95. It is hexagonal in form and presents three elegantly-constructed stories, each of which is finished by an embattled frieze; at every angle is a graduated buttress ornamented with foliated finials. In the second compartment appear the three statues of Queen Eleanor, the work of William de Ireland.

Another cross stood in the middle of Cheapside, a little to the west of Bow Churchyard, opposite Wood Street. It had originally the statue of the Queen, and in all respects resembled that at Northampton. The destruction of this famous cross took place in 1643.

Charing Cross was the last spot on which the body of Queen Eleanor rested in its progress to Westminster Abbey. The cross was octagonal in form and built of Caen stone, and in an upper stage contained eight figures. The steps and other parts of the fabric were made of marble brought from Corf, for which large sums were paid. Its demolition took place in 1647. The exact spot upon which it stood, according to some historians, is that occupied by the equestrian statue of Charles I.

The modern Eleanor Cross, in front of the Charing Cross Hotel, was erected in 1863, and is a reproduction as near as possible of the old one. It is from the designs of Mr. E. M. Barry, and cost nearly £1,800.

BANBURY CROSS.

It has been safely affirmed that, thanks to the nursery rhyme, this celebrated cross will never be forgotten while the English language lasts. The destruction of the original took place during a riot in the early part of the seventeenth century. Its restoration took place on the marriage of the late Empress Frederick, when it was resolved to restore the cross as the most graceful memorial of that event, and the present elegant structure of hexagonal form was erected from a design by Mr. Gibbs, of Oxford. It is 52 feet in height, of Bath stone, and is divided into three stories, or compartments.

IRISH CROSSES.

Ireland contains a great many stone crosses which are beautifully carved, and it is claimed that they constitute the finest monuments in Europe of the early Christian ages. In all the remains of ancient Irish art there is a peculiar style, the characteristics being interlaced ornaments; bands, cords, serpents, dogs, birds, even human beings are interlaced. There are also other modes — spirals, waves, zigzags, frets, etc. These ornaments display wonderful powers of invention and execution, and entitle the ancient Irish, in the opinion of Mr. H. O'Neill, to rank as the greatest masters of ornamental art t at ever existed.

About thirty-four miles from Dublin, in the County Louth, and some four miles from Drogheda, are situated the ruins of Monasterboice Abbey, consisting of two ancient churches, a pillar, and two very large crosses. The largest, or what is distinguished as the West Cross, is 23 feet high, and is a work of infinite beauty, as it stands amid the ruins of hallowed fanes and long-forgotten altars, presenting an object of the most contemplative interest. The other, known as the South-east Cross, is 17 feet high, and both of them are elaborately carved, while the material is a white silicious stone, close-grained, not unlike statuary marble.

The first panel on the lower part of the West Cross is greatly injured; it represents the soldiers guarding Christ's sepulchre. The second panel is understood to represent Christ's baptism, with the Holy Ghost descending, in what imagination may conceive to be the likeness of a dove. The four succeeding panels are supposed to represent the Transfiguration and other incidents relating to the Saviour. In the centre of the cross is Christ crucified, with the sponge and the spear-bearers.

The arms of the South-east Cross are 7 feet wide, and the shaft is 2 feet 3 inches wide at the base. This cross is composed of three stones; first, the base; the second reaches from thence to the top of the circle; and the third one completes the monument. There is an inscription at the base, "Or do Muiredach las in dernad Chrossa," meaning "A prayer for Murdoch, by whom was made this cross." This Murdoch referred to is supposed to have been Abbot of Monasterboice in A. D. 923. The three groups on the shaft of the cross and the fourth one over the Crucifixion seem to refer to one story; in the lowest group an ecclesiastic is attacked by two armed men; in the next, these men have become students or ecclesiastics; in the third, the ecclesiastic resigns his staff to one and his book to the other.

The Cross of Cory is a beautiful processional cross originally made for the church of Tuam, seat of the Archbishopric of Connaught, and for Muiredach O'Duffy, who died in the year 1150. It was made to enshrine a portion of the true cross by order of King Turlough O'Conor, as may be learned from an entry in the "*Annals of Inisfallen*," A. D. 1123. The annalist states: "A portion of the true cross came into Ireland, and was enshrined at Roscommon by Turlough O'Conor." This statement is supported by inscriptions along the sides of the cross. The shaft of this cross is formed of oak, covered with plates of copper outside. It was concealed at the time of the Reformation and found early in the last century in an oaken chest. It was presented to the museum of the Royal Irish Academy in 1889.

The form of the Irish cross, being that of the Greek cross with arms projecting outside the circle and shaft elongated, is a curious combination of the Greek and Latin cross, and seems symbolic of the whole subject of Irish ecclesiastical art, which, from its very beginning, shows Byzantine and Latin elements commingled. . . .

THE CROSS IN HERALDRY.

In the heraldry of the Middle Ages the form and enrichment of the cross was treated in many ways.

The English cross of St. George is a plain red cross, set erect on a white ground. The Scottish cross of St. Andrew is a plain diagonal cross on a blue ground. The Irish cross of St. Patrick is a plain diagonal red cross on a white ground. . . .

The cross of Passion, when erected upon three steps, is known as the cross of Calvary. The steps allude to the three Christian virtues — Faith, Hope, and Charity.

Many wealthy merchants in the Middle Ages, both in England and on the Continent of Europe, having no armorial bearings, used as their signet, or marks of cognizance, certain monograms. These were invariably of the cross in combination with some other emblem, such as the circle, referring to the globe, the pennon or flag of a ship, or the vane of a weathercock, alluding to the prosperous gales upon which depended the success of their navigation.

MARKET-CROSSES.

The privilege of holding markets was in olden times granted to the monasteries, and the cross was erected, not only as a sign of their jurisdiction and power to receive tolls, but also as a pulpit for occasional religious exhortation. The influence of the cross was acknowledged by the traders, for they were in the habit of appealing by oath to that sacred image, under whose shadow they stood, that their goods were honestly come by and up to the mark. At first these market-crosses were only single cruciform shafts elevated on steps, but after awhile they became decorated with pinnacles, niches, etc., and then later on projections, or arches, were erected to shelter the people from the weather. The cross at Cheddar, for instance, shows the original structure as having been at first merely a simple shaft raised on steps with lateral piers, and a roof was erected at a later period. At Winchester there is still a fine cross known as the Butter Cross, which is on the site formerly occupied by the old market-cross.

The great market-cross of Chichester is another of the very few structures of this kind now standing, and was completed by Edward Storey, Bishop of Chichester, about the year 1500. The worthy prelate left an ample estate to keep his practical monument in repair. The cross is octagonal in plan, and consists of an open arcade of flat, moulded arches with ogee-crocketed heads, flanked by buttresses, terminating in crocketed pinnacles. The clock is a later addition, being the gift of Dame Elizabeth Farrington in 1724, "as an hourly

memento of her good-will." The total height of the cross is 50 feet, and in 1724 it was completely restored at the expense of Charles, second Duke of Richmond.

With regard to the market-crosses of Scotland, there seems every reason to believe that these had their beginning in the cross ecclesiastical, which was erected as the visible ensign of the Christian faith, and that the earliest ones were of wood, but as the missionaries felt their position in the country more assured they erected crosses of stone which at first in shape resembled the wooden crosses. Of the ornamental stone cross ecclesiastic, which succeeded to the plain stone cross of wooden type, many elaborately carved examples still survive. Chronologically parallel with the cross ecclesiastic, for a very long period before the Restoration, the municipal, or market, cross existed where merchandise had to be presented for sale, and where proclamations were made. The market-cross was also the scene and the centre of public rejoicings of all kinds as well as the theatre of public punishment and shame.

The market-cross of Edinburgh was properly that which ranked first in importance in royal and other proclamations. After that, perhaps, no market-cross in Scotland was associated with so many stirring events of public interest as that of St. Andrew's, which was removed in 1768. The market-cross, as an institution, has now all but fallen into desuetude.

A SEWAGE-DISPOSAL SYSTEM FOR A COUNTRY-HOUSE.

MY work as sanitary engineer brings me in constant touch with the architectural profession, and I have found that the question of a properly designed sewage-disposal system for a medium-sized and moderate-priced country-house is rarely thought of, on account of the cost.

It is with this in mind that the writer shows herewith a sub-surface disposal-system for a house of three bath-rooms, of about twenty-one fixtures, and which has been built within sixty miles of New York City. The house contained the following fixtures: —

Basement: one water-closet, one sink, one set (three) laundry-tubs. First story: one water-closet, one pantry and one kitchen sink, one basin. Second story: two water-closets, two baths, one slop-sink, five basins. Third story: one water-closet, one bath, one slop-sink, one basin. A total of twenty-one fixtures.

A sewage-disposal system may be located at any distance from the house, depending upon the size of the property; in one case, the basins were but 60 feet from the house; in general, however, 200 feet is a good distance.

The sewage-disposal system under discussion consists of a 5-inch sewer of earthenware pipe, with cemented joints, running from house to the basins; the two settling-basins with the adjoining siphon-chamber; the 4-inch line from the siphon to the irrigation-field; and the irrigation-field. [See Illustrations.]

The house-sewer is laid with great care. The settling-basins consist of two chambers built to contain sewage without a possibility of leakage. The first basin is to be of sufficient size to contain one day's supply of sewage from the house, the second basin to be of somewhat large size. The siphon-chamber contains the siphon; and is for making any needed repairs to the siphon and for inspection. The line from siphon to irrigation-field may be of any length, but in this case was about 60 feet long, and of 4-inch earthenware pipe with cemented joints. The irrigation-field consists of a series of lines of small porous irrigation-tiles, in this case 3-inch, laid about 10 inches below the surface of the ground and well covered by small stone.

The general dimensions and quantities shown are from data obtained by the writer from observation, and are used in all his works with but slight modifications.

The theory of sewage-disposal by sub-surface irrigation may be thus summed up: The sewage from the house is to be disposed of as soon as possible. The sewage reaches the first of the settling-basins, where bacterial action immediately takes place, breaking down the organic bodies. In this basin precipitation occurs. The now somewhat clarified sewage enters the larger basin, where another period of rest takes place. When the sewage in this basin has reached a certain determined height, the seal in the siphon in the adjoining chamber breaks and the entire contents of the basin is sent to the irrigation-field. The small tile, having a covering of broken stone, are surrounded by a large volume of air, which immediately attacks the sewage, throwing off hydrogen and nitrogen, the latter being eagerly sought after by the roots of the plants in the soil above.

The irrigation-field should be selected with great care. It should have a southern exposure, with sandy soil, and not be near a stream or brook. Should the soil be poor, heavy or of clay, then the "field" should contain more tile. Should shaded land only be available, then, too, more tile will be necessary.

The method of running the lateral irrigation-tiles is entirely governed by the contour of the surface of the ground. They may be laid in curved lines, or in lines at right angles to the main distributor, or, again, the distributor may be branched, and two "fields" may be formed. The lateral tiles should have a fall of about 3 inches per hundred feet, the main distributor a fall of about 6 inches per hundred feet.

The lateral 3-inch tiles are laid with caps and gutters, the former keeps small stone or earth from entering the pipe and the latter provides a permanent bed for the pipe. They provide an easy means for inspection or for making repairs or additions.

It often happens that on account of the flatness of a tract of land, the use of a siphon on account of its depth is out of the question. In such a case both basins should be built much larger, and all openings should be provided with screens of ¼-inch mesh, of galvanized ware, and the sewage be allowed to enter the 3-inch lines direct; the field, too, should be made much larger.

The cost of the above work, the settling-basins and the field only, was about $230.

WM. C. TUCKER.

BOOKS AND PAPERS

IT is a little startling to any one who has seen the long rows of books in every library treating of Italian sculpture, Italian art, the Cinque Cento, the Renaissance in Italy, and the histories of Florence, Milan, Rome, Venice and Sicily, to hear that there is no history of Italian architecture in English; and architects, most of whom consider themselves tolerably familiar with all the principal buildings in Italy, will, at first, be inclined to question the statement with which Mr. Cummings introduces his book;[1] but, on reflection, it will probably appear that the knowledge which most people possess of the best-known buildings in the world is a collection of fragments, picked up, bit by bit, from local annals or from critical essays; and that a connected history of the development of Italian architecture, from the decadence of the antique to the Renaissance, has not existed, at least in a form available for English readers, until Mr. Cummings undertook to supply the want. This task he has fulfilled with the most painstaking care, and with corresponding success. Not only have the abundant sources of fragmentary information been collated, and what they could furnish properly connected with the rest, but Mr. Cummings has examined most of the buildings of which he speaks on the ground, with his manuscript in his hand, modifying where his trained intelligence showed him that the accepted conclusions were questionable, and, in many cases, adding observations of the greatest value and interest. In these, as well as in the clear presentation of the facts, as distinguished from theories and errors, in connection with familiar buildings, the professional reader will find great pleasure, and every reader must be charmed with the pure English in which the ideas are expressed, and with the beautiful and well-selected illustrations.

Mr. Cummings begins with the catacombs, in which the origin of Christian architecture is now generally sought, giving a particularly interesting description of the chapels built either in the catacombs or in close connection with them. From these it is an easy transition to the basilicas; and, in fact, the first Christian basilicas were themselves built in connection with catacombs or with other places of sepulture of martyrs or saints. Mr. Cummings does not go so far as Mr. Lowrie and the Germans in rejecting the theory of the adaptations of the judicial basilicas to the uses of Christian worship, but he says that the extent to which the former were copied in the Christian basilicas "has been greatly overstated." He mentions that the basilica, or hall of justice, in Nero's palace of the Lateran, was transformed under Constantine into a Christian church, in connection with the papal residence established at the same time in the palace; and it is not likely that so conspicuous an example would have been wholly ignored.

The basilicas lead naturally to the great churches which have succeeded them, and which, in many cases, stand on the site of those of Constantine and his successors. It is difficult to say in some cases how much of the original building still remains in the present structures, and it is necessary, for the proper study of the style, to show photographic plates of St. Paul without the Walls, rebuilt since 1823, close to those of St. Agnes, perhaps fifteen hundred years older; but St. Paul was rebuilt substantially in the old form, and by no other method could the architectural development of the characteristic Roman basilica have been shown.

The period of basilica-building in Rome was followed by the brilliant reign of Theodoric in Ravenna, and the construction of the remarkable group of churches, half Roman and half Byzantine, which still stand to attest the vigor of the new Gothic element which had invaded Italy. Every one knows the magnificence of the Ravenna mosaics, but it is, perhaps, not so much in these as in the curious blind arcades at the top of the walls of the churches, and in certain other Northern characteristics, that we trace the artistic movement which developed, long afterwards, into the Romanesque of North Italy.

The power and wealth of the Gothic conquerors are strikingly shown by these and the other splendid buildings erected under Theodoric and his immediate successor, yet, a few years later, the body of Theodoric was taken from his magnificent mausoleum, the roof of which is of a single stone, 35 feet in diameter, and was carried by the remnant of his people, fugitives before the Byzantine armies of Belisarius and Narses, and thrown into the centre of Vesuvius by the handful of despairing Goths who had escaped the sword of the Greeks.

[1] "*A History of Architecture in Italy*," from the Time of Constantine to the Dawn of the Renaissance. By Charles A. Cummings, Fellow of the American Institute of Architects. With nearly 500 illustrations. New York and Boston: Houghton, Mifflin & Co. 1901. In two volumes. Price, $7.50.

The extirpation of the Goths, who, it is interesting to remember, came from the island of Gothland, in the Baltic Sea, and were so closely related to our own Anglo-Saxon ancestors that the translation of the Bible made by the Gothic bishop Ulfilas is easily understood by English readers, was followed by the invasion of the Lombards, who fixed themselves firmly in Northern Italy. Mr. Cummings presents an interesting study of the Lombard institutions, and the development of the organization of mechanics through which the Lombard manner of building was formed, and carried over nearly all Italy. It is remarkable, considering the original barbarism of the Lombards, that their masons very soon undertook the vaulting of their churches, using independent ribs, both transverse and diagonal, and even anticipating the French architects of three or four centuries later, by slightly pointing the diagonal ribs, to give greater stability to the vault.

After a long and most interesting chapter devoted to the Lombard architecture and the Byzantine influence upon it and other Italian work of the period, notably in Venice, Mr. Cummings turns to what he calls the Central Romanesque, or that of Tuscany, and then to the South, giving a great deal of new and valuable matter about the curious Norman-Byzantine-Moorish architecture of Sicily and Apulia. This brings us to the Gothic; and here, although the ground is tolerably familiar to most of us, he supplies much new and interesting detail. Speaking, for example, of San Petronio, at Bologna, the finished portion of which is, perhaps, the most beautiful piece of Gothic work in Italy, he mentions the competition which was held, about 1535, when the Renaissance was in its full glory, for designs for completing the front of the Cathedral, nearly all of which is still in rough brickwork, the Gothic facing of the fourteenth century never having been carried up above the arches of the doors. Palladio, Vignola, Baldassare Peruzzi, Giulio Romano, and some twenty-five others of the most distinguished architects in Italy competed, and their drawings are still preserved in the sacristy of the cathedral. It is remarkable that Baldassare Peruzzi and Giulio Romano sent in Gothic designs, although both of them were among the most distinguished leaders of the Renaissance, and, at this period, the Gothic style had been, for nearly a hundred and fifty years, regarded in Italy as antiquated and barbarous. Apparently, these great men, recognizing and respecting beauty, even in a discredited and unfashionable style, had, like true artists, chosen to complete the work of another, in preference to displaying their own skill in a style of which they were recognized masters. None of the designs were carried out, and the church remains with its rough brick front to this day, but it is much to be wished that the competitive drawings could be published for the benefit of the community.

It has probably already occurred to the reader of these notes that Mr. Cummings's volumes would make an excellent companion, either for an architect on a vacation tour in Italy, or for a student intent upon serious work among Italian architecture; and they are in every way admirably adapted to such a purpose, being moderate in size, although not so small as to spoil the illustrations, and as light as the quality of the paper required for proper rendering of the illustrations will permit, while the general reader, and the lover of beautiful books, will find in them perfect printing, both of text and illustrations, good binding, and excellent proof-reading. The last is a quality of much greater value than publishers in general seem to suppose; and it is a satisfaction to the professional man to be able to read about Italian architecture without stumbling over references to "Pope Damascus," and the "Palace of Diocletian at Spoleto," which disfigure a recent book on the subject, otherwise in every way admirable.

It is not only with the greatest interest and pleasure, but with no small pride, that we look over Mr. Lowrie's book,[1] one of the first important fruits of the opportunities given by the American School for the study of antiquity at Rome, and a work which would do honor to any scholar, of any nation. For the general reader, no more attractive theme could have been chosen in the whole range of archæology. Notwithstanding the opinion of the distinguished divine who came to the conclusion that martyrdom was merely a fashionable craze among the early Christians, and that they rather enjoyed being devoured, the world at large, both Protestant and Catholic, cherishes with daily increasing veneration the memory of the people who met death, kneeling hand in hand in the arena, to bear witness of their belief in the crucified carpenter's son, and their devotion to his doctrine of love, and welcomes with eager interest everything that can bring us nearer in imagination to the love-feasts, in which masters and slaves joined, in humble obedience to the words of their Master, and to the burial services in which, for the first time, perhaps, on earth, the sorrow of separation was turned into joy by confidence in a Divine revelation of immortality. In this field there is much work yet to be done, but it is a matter of congratulation for readers of English that the investigations which Lanciani, in his "*Christian Rome*," hardly more than suggested, should have been carried on with such skill and learning, as well as with such sympathetic insight, as Mr. Lowrie has shown. It is hardly necessary to say that the five hundred and fifty miles of galleries in the Roman catacombs, to say nothing of those in other parts of Italy, and the thousands of Christian monuments, as yet almost unknown, in Syria and Africa, will furnish, for many years to come, new illustrations of the faith and life of the early Church; but these will be much more correctly and easily interpreted if the preliminary steps in investigations of the kind are carefully taken.

Naturally, the most characteristic works of the Christians of the early Church in Rome are found in the catacombs, and Mr. Lowrie begins his book by a most valuable chapter on the origin and use of these subterranean burial-places, upsetting, in the course of it, some cherished theories in regard to their having been abandoned quarries, utilized by the Christians for their purposes. As all the Roman catacombs are cut in a granular tufa, useless for construction of any kind, it is evident that they must have been excavated with a definite intention; and, as nearly all of them are comprised within the boundaries of what were then, in all probability, enclosed gardens, the inference is that they were, in most cases, formed by permission of the owner of the ground, who may have been a convert, or, at least, a favorer of the new doctrine; and the few instances in which the catacombs proper connect with sand-pits or quarries seem to have been due either to the desire to utilize a disused space for disposing of the material excavated from the new galleries, or, possibly, in some cases, to the wish to make available an additional mode of egress in times of persecution. The rock, within the boundaries of the lot devoted to the burial-place, is perforated with galleries according to a definite plan, often in two or more stories; and the recesses, or *loculi*, in which the bodies of the dead Christians were laid, were regularly cut, either in the walls of the passages, or around little chambers, apparently devoted to families, as the case might be. So far as the means of the surviving relatives would permit, the burial-chambers, or the covers of the *loculi*, were decorated with painting or sculpture of a character which is artistically of the greatest interest, forming, as it does, a step in the transition between the refined but unsympathetic perfection of the antique and the expressiveness of mediæval art. It is true, as Professor Wickhoff shows in his beautiful work on "*Roman Art*," that a great change came over even Pagan sculpture under the Empire, in the direction of freedom and naturalism in the study of ornament, and of expression in portraiture; but whether this change was due to the influence of Christian artists on their Pagan brethren, or whether the Pagans set the fashion for the Christians, or whether both Pagans and Christians were unconsciously affected by the new spiritual light which had begun to shine in the Roman world are questions which people will long take pleasure in trying to answer.

After the catacombs, the study of which forms the natural introduction to that of ancient Christian art in general, Mr. Lowrie takes up the architecture of the basilicas and other ecclesiastical buildings of the early Church. In regard to the origin of the Christian basilica, he, like other recent writers, rejects entirely the theory that it was simply an adaptation of the judicial basilica familiar in all Roman towns. Those of our readers who have studied the history of architecture from the ordinary text-books will remember that they agree in asserting that the decay of the Roman power under the later Empire, and the crowding of the rural population into the capital, had caused the abandonment of the public buildings of many provincial towns, and that the Christians, after their worship was permitted by law, appropriated the disused basilicas, or court-houses, for the use of their congregations; and even the details of the civil basilicas, such as the seats for the judge and the lawyers in the apsidal "tribune," corresponding to those of the bishop and inferior clergy in the sanctuary of the Christian church; the altar in front of the tribune, where the judges took their oath before the assembled people to execute justice, corresponding to the primitive position of the altar in the Christian churches; and even the "cancelli," or railings, which divided the tribune from the main body of the building in the judicial basilicas, as they still do the chancel from the nave in ecclesiastical buildings, are given in most books with such completeness that it is difficult to question the analogy. Mr. Lowrie, however, says that there is not a single instance recorded in the history of the Church in which a secular public building of this kind was appropriated to Christian worship, while all the secular basilicas, the ruins of which still remain, show a disposition of plan quite different from that familiar in the Christian basilicas. It is true that there is a striking coincidence in name between the pagan hall of justice and the Christian place of worship, but he says that the word "basilica," or "house of the king," or "master," was used so widely under the Empire to designate any state apartment or place of public business, that its adoption by the Christians to denote the house of their Divine Master was quite natural. Instead of the civil basilica, he thinks that the type of the Christian house of worship is easily found in the ordinary Roman or Italian dwelling. Every such dwelling contained, as its principal apartment, an atrium, or hall, generally surrounded by a colonnade, which served for the reception of friends, and undoubtedly, for the meetings of the little congregations of Christians in the earlier period. In the larger houses, the atrium formed a preliminary reception-room, intended particularly for strangers, or visitors on matters of business, while the family and its friends met in the peristyle, a larger room, also surrounded by a colonnade, beyond the atrium, and connected with it only by a narrow passage. Whether the atrium or the peristyle was the family reception-room, the arrangement was nearly the same, a recess, or tablinum, in which stood the family altar, always opening from it, on the side facing the entrance, while two other recesses, or small rooms, opening from the sides of the main room, at the upper end, near the altar, usually contained portraits of the ancestors of the family. These "wings," or side rooms, developed very naturally

[1] "*Monuments of the Early Church:*" By Walter Lowrie, M.A., late Fellow of the American School of Classical Studies at Rome. New York: The Macmillan Company. 1901. Price $1.75.

into the transepts of the Christian church, which have no counterpart whatever in the civil basilica; and the colonnades of the atrium or peristyle, separating the central space from an encircling passage-way, served, probably, in the churches, as in dwellings, for a needed separation between the professed Christians who participated in the service in the central space and the interested spectators just outside the columns. Even the less simple dwelling-house plan, including both atrium and peristyle, was transferred to the larger churches, particularly in the East, where the atrium became the "narthex," or porch, in which the unbaptized remained, seeing and hearing what they could of the service through the open doors. The tablinum, or altar-recess, was transferred, almost without change, to the larger building, as were also the transept-like wings, which, in the earlier basilicas, were proportionally small, and seem to have been used as sacristies or chapels. The main difference between the Christian basilica and the domestic reception-room lay, of course, in the extension of the colonnade of the former vertically, in the form of a clerestory wall, in such a way as to permit the roofing of the nave, at the same time that light and air were admitted by the clerestory windows. Mr. Lowrie thinks that the peristyles, or, at least, the atria, of dwellings may sometimes have been covered and lighted in the same way; but, although this seems perhaps questionable, it is certain that such an expedient would readily occur to the bold and resourceful Roman architects as soon as the proposed dimensions of such a building made something of the kind necessary.

We should be glad to follow our author farther into his deeply interesting study of the development of the Christian house of worship, as well as to say something about the succeeding chapters, on painted decoration, sculpture and vestments in the early Church, but space does not permit, and we must refer our readers to the book itself, in which students of the history of art will find equal pleasure and instruction.

SOCIETIES

DETROIT ARCHITECTURAL CLUB.

THE Detroit Architectural Club, through the Educational Committee, instituted some time ago a competition among its members, the subject being a design for a country residence to be located in a suburb of Detroit on the shore of Lake St. Clair, the lot to have a lake and street frontage of 200 feet. Besides the residence the sketches were to include buildings for saddle-horses, hounds, and automobiles, a greenhouse and a boat-house. Numerous designs were submitted. At the last regular meeting of the Club, Architect J. W. Case gave a criticism on the different designs, awarding First Mention to J. J. Fraunfelder; Second Mention to George V. Pottle; prize for First Mention being a handsome bronze medal; for Second Mention, a set of books.

A competition has also been held to procure a design for a book-case to be placed in the club-room. Architect Albert Kahn gave a criticism on the drawings submitted. The design submitted by A. Eisen was adjudged as the winning design.

The Club has now constituted and under way a competition for a band-stand to be located on Belle Isle. The construction for same may be of stone, brick or terra-cotta. All drawings must be in the hands of the Secretary on Monday, February 24, 1902. Architect William B. Stratton will judge them and render criticism.

A. EISEN, *Chairman Publicity Committee.*

ILLUSTRATIONS

[Contributors of drawings are requested to send also plans and a full and adequate description of the buildings, including a statement of cost.]

NEW WILLARD HOTEL, WASHINGTON, D. C. MR. H. J. HARDENBERGH, ARCHITECT, NEW YORK, N. Y.

THE interior of the building, decoratively considered, has received the following treatment: —

Dining-room: Woodwork of dark English oak; columns of dark green (Alps-green) marble; caps, gold; ceiling-beams of dark oak; panels and decoration in greens, brown and gold. Palm Court: Pompeiian decoration. Main Lobby: Columns and pilasters of Siena marble; caps, gold; walls of Venetian red; ceiling in buff and gold. Ball-room: Woodwork enamelled, ashes-of-rose with delicate pink panels. Banquet-room: Woodwork enamelled ivory-white with delicate green panels.

SCALE DETAILS OF THE SAME.

RESIDENCE FOR MRS. WILLIAM L. SKINNER. MESSRS. VAS & TAKACH, ARCHITECTS, NEW YORK, N. Y.

THE construction of concrete houses has hitherto been in disfavor owing to the lack of a suitable style which could be properly shown by such material. In the construction of the residence as illustrated, the most stringent rules of architecture have been obeyed; that is to say, stability, usefulness and beauty have been obtained by the combination of the style with the material best suited to the beauties of that style. The walls, floors, partitions and roof will be a combination of iron and concrete. The combination has been so designed that the floors are never more than nine inches thick. The wall-construction is the same as the floor-construction except that a hollow space of two inches is provided, thus securing a minimum of material and the greatest amount of strength and comfort to those who occupy the house. The most novel feature of the house is in the finish of the floor-surfaces. No wood whatever will enter into the construction of the floors. On the top of the concrete-and-iron combination, there will be a finish in natural cement, which will be continued up on the partitions and walls, to form a moulded base-board. Between the base-mouldings and on the surface of the cements will be laid thick linoleum of suitable design to harmonize with the decoration of the room in which it is laid.

A SEWAGE-DISPOSAL SYSTEM. MR. W. C. TUCKER, ENGINEER, NEW YORK, N. Y.

NOTES AND CLIPPINGS

THE DESPOTISM OF TRADE-UNIONS. — At Franklin and Marshall College Chapel recently, George F. Baer, President of the Board of Trustees of the College and President of the Philadelphia & Reading Railway and the Central Railroad of New Jersey, delivered a lecture on "Work is Worship," in which he severely denounced labor-unions. He said in part: "To-day there is no greater absolute despotism and tyranny on the earth than the power which forbids a man to work because of some other man's quarrels. In some trades employers are not

permitted to employ workmen without labor-organization cards. Union men will not work with non-union men. Was ever greater tyranny practised by one set of men over their fellow-men? So apathetic has the public conscience become to the terrorism, tyranny, and lawlessness of labor organizations that not only the politicians, who are seeking votes, but well-meaning men, who ought to know better, cry aloud against the decrees of the courts when the principles of Constitutional liberty are invoked in legally established tribunals to restrain the lawlessness of labor organizations. Labor may organize, but it may not tyrannize. Labor organizations hitherto have failed because they have entirely overlooked these simple fundamental truths. The modern theory of labor organizations seems to be that the employer and employé are to be divided into two great hostile camps, armed and fully equipped, at a given signal, to engage in industrial war. Peace is only to be a temporary thing, brought about by formulating a truce between the two contending armies, which shall terminate at the end of the year. In the meantime, the leaders of the hostile camps are to be fully occupied during the whole of the year in adjusting the thousand and one vexatious misunderstandings as to the true meaning of the terms of the truce. The business is to be carried on by divided authority, each hostile camp having representatives to determine when and how the work shall be done. This is violating the old rule that 'No man can serve two masters.' If it continues, the present industrial supremacy of the United States will soon be a thing of the past, and we will share the fate of England. It is beyond question true that the primary factor in the decadence of England's industries has been the arbitrary exactions of trades-unions. The London papers continue to call attention to the crisis in British industry, and practically agree that British workmen through their trades unions are ruining not only themselves but the industry of the country. — *Exchange.*

Lord Leighton's House declined. — The *Times* says that the Kensington Borough Council, on the recommendation of the Libraries Committee, has declined to proceed further for the transfer of Lord Leighton's house. The proposal to hand this beautiful building to the public has therefore fallen through.

State Highway Work in Massachusetts. — In the last season's work of the Massachusetts State Highway Commission some 27 miles of new roads were added to the State's system, these and the more extensive work done on old roads being the proceeds of the $500,000 which the Commission has decided to spend a year. Since the plan of State activity in the construction and supervision of highways was adopted in Massachusetts 888 miles of road have been built, or about half of the 10 per cent of all roads in the State, which, to live up to the French standard, the Commission will have to improve. Most of the main lines, such as the one from Boston to Springfield, from the end of Cape Cod to Fall River, from Pittsfield to the New York State line, the northern route from Boston west, the roads from Boston to Lowell, and from Boston to Providence, are being advanced in satisfactory fashion toward completion. Especially ready coöperation with the work of the Commission has been carried on by the towns in the southeastern part of the State, but a growing interest in the enterprise of the State and an increased disposition to profit by the Commission's experience and construction have been displayed by communities in all sections. Much of the new road built in Massachusetts has cost about $5,560 a mile, though the average for the State, owing to the grades met in many sections, amounts to about $7,500. The material was macadam. Maintenance charges run about $100 a mile a year. The Commission has succeeded in keeping costs something under the levels at which they began, and this has helped to win popular approval for the work. Concerning the benefits coming from it, the Massachusetts folk seem to be of one mind. Time saved in travel, less strain on horses and vehicles, economy of power in transit, this last often reaching 33, and even 50 per cent, cheaper and more expeditious access to markets, and more trade and benefit from casual visitors, or more or less permanent residents, attracted by the excellence of the roads, are among the advantages claimed, and apparently with justice, as the results of the Commission's work. — *N. Y. Evening Post.*

Proposed Statues of Sherman and Longfellow. — A bill has been introduced in the Senate by Mr. Foraker providing for the erection of a statue of the late John Sherman in Washington, to cost $50,000. Mr. Wetmore, of Rhode Island, submitted favorable reports from the Committee on the Library, on resolutions authorizing the selection of a site and the erection of a pedestal for a bronze statue in Washington, in honor of Henry Wadsworth Longfellow, to cost $4,000, and for completing a monument to the memory of Dorothea Lynde Dix, for which $10,000 is appropriated. — *Exchange.*

Gigantic Dynamos for Niagara. — The *Electrical World and Engineer* contains an article commenting on the notable development of the Canadian Niagara power-plant. The article is in part as follows: On the American side, where all the work has been done hitherto, newer machinery of the very latest type of its class has just been ordered, while for the hitherto unattempted utilization of the water-power on the Canadian side of the great cataract, the Niagara Falls Power Company has just given a contract to the General Electric Company for three immense units of 10,000 horse-power each. These machines are not only to be the largest electric-generators ever built, but they will embody features of design of the utmost significance, altogether aside from the fact that the new work is to be done under American initiative with American capital and employing American apparatus. We understand from the Canadian Niagara Power Company, which has just awarded the contract, that these gigantic generators are but the first units in a plant which will probably reach an aggregate of 200,000 horse-power or more within a very few years. The power-house is to be situated on the flat land adjacent to the Dufferin Islands near the river, less than a quarter of a mile above the Horseshoe Falls. A wheel-pit is being excavated in the rock, which will be connected by a tunnel tail-race to the gorge below the Falls. The dynamos will be placed at the surface-level as before, being connected to the turbines by long vertical shafts, which extend to the bottom of the pit, where the turbines will be situated. The machines contracted for are, as already noted, far larger in capacity than any electric-generators previously built. They are also remarkable on account of the high speed at which they will operate, 250 r. p m., the same as that now used with the smaller 5,000-horsepower generators on the American side. This, it may perhaps be worth noting, is the third large contract for generators at Niagara Falls which has been awarded to the General Electric Company during the past twelve months. All will be built at Schenectady.

The proposed Anglo-American High Building in London. — The London County Council refused January 20 the application, in behalf of an Anglo-American syndicate, headed by Sir Charles Rivers Wilson, for a 999-year lease of a site on the north side of the Strand, with a frontage of 750 feet, and with still larger frontages on the new streets coming out on the Strand, for the erection of an office-building on American lines, to cost $2,000,000. The Council took the ground that such a length of tenure practically amounted to selling the freehold, which was not within its power; but announced that it was willing to negotiate on the basis of a 99-year lease. — *Exchange.*

Rare Finds in Armenia. — The interest of the German Government in the Bagdad Railway has led it to dispatch important missions to Armenia for the purpose of making archæological explorations in Armenia. The first of these expeditions was intrusted to Dr. W. Belck alone, and in 1898 and 1899 he was accompanied by the Assyriologist Dr. C. F. Lehmann. The report of these expeditions has just been issued, and the results to science are most important. The first indications of a civilization in the mountain-lands bordering on Lake Van were made known by the French traveller Dr. Schultz, who copied a number of inscriptions on the rocky walls of the fortress of the city of Van. Schultz, unfortunately, was killed by the Kurds, but his diaries and copies of inscriptions were recovered and published by the French Government in the *Journal Asiatique.* Layard, who visited Armenia in 1849, copied a number of inscriptions, and Rassam, who made several visits to the country and excavated at Toprak Kaleh, the ancient palace of the Vannic kings, copied or took casts of several more, but the work of the German expeditions has greatly increased our knowledge of the country. The members collated all inscriptions previously copied, and increased the material for the study of ancient Armenian history by nearly two thousand lines — including the discovery of a most important and fairly lengthy bilingual inscription in Assyrian and Vannic. The most important result of the expedition has been to define clearly the extent of this empire, which had almost entirely disappeared from the field of history. The capital city was Van, on the lake of that name, called Dhuspas — the Tosps of the classics — but the royal residence seems to have been at Toprak Kaleh, called at a later period "Rusas town." The northern boundaries of the empire are uncertain, but several inscriptions were found in Russian Armenia. On the east the inscriptions were found as far as Lake Uromiyeh, and one on the rocky heights near Rowandiz, on the summit of the Pass of Keli-shin, 12,000 feet above sea-level. This inscription was first discovered by Sir Henry Rawlinson, and was set up during the joint reigns of the Kings Ispunis and Menuas, about B. C. 800. Westward, on the rocks at Palu, on the Euphrates, near Malatiyeh, the inscriptions of Menuas are also found. — *Paris Messenger.*

How Italy deals with Railroad Strikers. — The *Official Journal* of January 25 announces that the Government has taken a decided stand in view of the rumors of an impending strike upon all the great railways in Italy. The Cabinet announces that it cannot consider a railway strike, affecting, as it does, great public interests, in the same category with a strike of ordinary workers, but will class such an action as a strike of public servants, punishable under the penal code. While determined not to allow a railway strike, the Cabinet recognizes the right of the working-classes to improve their own condition, and therefore the Government has approached the railway-companies with a view of obtaining the desired concessions, which it is confident it can do. — *Exchange.*

Art in French Toys. — The thorough manner in which the French Government interests itself in art matters is once more shown in the prizes offered by the city of Paris for the best new toys seen at the great New Year's Day sale along the boulevards, when miles of booths devoted to the display of toys and holiday wares are erected for a fortnight. Twenty prizes went to the designers or inventors of toys, not exceeding three francs in value, which showed the most originality and artistic taste. — *N. Y. Evening Post.*

Art in the Common Schools. — A few days ago a little boy came into a certain library with a penny picture of a cold, flabby modern German Madonna, and said to the librarian, "Will you please tell me if this is beautiful?" The librarian told him that she thought it hideous. "Oh, I'm so glad," said the child. "Teacher gave us each a picture, and told us to live with it until we could see all its beauty, and I've lived with this for three weeks, and the more I look at it the homelier it seems to get." — *Library Journal.*

The Cresson Bequest to the Pennsylvania Academy of Fine-Arts. — By the will of Mrs. Priscilla P. Cresson, of Philadelphia, a trust-fund of $500,000 is created, the interest to go to the Pennsylvania Academy of Fine-Arts to pay the expenses of promising students who wish to study art abroad. Mrs. Cresson's husband died in 1899 and left $200,000 for the same purpose. — *Exchange.*

AN important competition is to be closed April 1 next, for the statue or memorial to General Grant, to be erected in Washington. The competition was announced a year ago, and those wishing to compete were required to send in their names before January 1 of this year. Thirty-six artists have responded to the invitation, including Cyrus W. Cobb, C. E. Dallin, T. Massey Rhind, Franklin Simmons, F. W. Ruckstuhl, Henry Niehaus, John J. Boyle, H. K. Bush-Brown and other sculptors, and, among architects, Warren, Wetmore & Morgan, Lord & Hewlett, George Keller, Ackerman & Ross, Lopez, Robb & Hornbostel, and Clarence Luce. Competitors are required to submit models, at a scale of one inch to the foot. Under the terms of the competition, all the models are to be exhibited for two weeks, and six are then to be selected, the authors of which will be paid one thousand dollars each. The final selection, carrying with it the execution of the work, will be made from among these six.

ACCORDING to the newspapers, the Exposition at Charleston, South Carolina, has not, so far, been very successful. The attendance is small, and almost exclusively local, the Northern tourists who were expected to flock to Charleston being very conspicuous by their absence. It is possible that the visit which President Roosevelt has promised to make will do something to revive outside interest, and, as the season advances, many of the Northerners now in Florida are likely to stop over a day or two in Charleston on their way home; but, the prospect certainly is that the South Carolina Exposition will suffer, even more than the one at Buffalo did, from the weariness and indifference with which most people now regard great exhibitions of any sort. To a certain extent, also, the Exposition at Charleston is at a disadvantage, as one anywhere in the far South would be, from the prevailing opinion in the North and West in regard to Southern civilization. Of course, the few Northerners who have friends or relatives at the South know that South Carolina, Georgia, Alabama, Mississippi and Louisiana are full of intelligent and good people, whom we may well be proud to own as fellow-citizens; but the average Northerner, who gets his ideas of conditions south of Mason and Dixon's line from the newspapers, firmly believes that the people of the South find their principal amusement in burning negroes alive, or hanging them and "riddling them with bullets," with, occasionally, a "race war" to call out a large number of people. It is true that these occurrences take place in the remote country-districts, and only involve a small fraction of the population, and it is quite possible that the people hung or shot or burned deserve their fate; but the undisputed fact that such things happen almost daily in the South, and the knowledge that a Governor of a Southern State has found it necessary, in an official message, to deplore the carelessness in such matters which led some of his fellow-citizens to lynch a man for a crime committed at a distance, and then, after packing the corpse in salt, and forwarding it for identification to the scene of the crime, to find out that it was the wrong man, have given Northern people a horror of what they suppose to be Southern ways which it will take generations to overcome.

THE National Sculpture Society, which has not held an exhibition for three years, proposes this year to have two, one in April and the other in October. The April exhibition is to be held at the rooms of the National Arts Club, 37 West Thirty-fourth Street, New York, and will be devoted to statuettes, medals, bas-reliefs, small busts, and sketches or models for larger works. These smaller objects do not get the attention that they deserve when shown with life-size or heroic subjects, and for this reason the Society has decided to try the experiment of exhibiting them separately. In October, an exhibition of larger works will be held in the Madison Square Garden, in connection with the exhibition of the New York Florists' Club. Every one remembers the success of the Society's last exhibition, in which the subjects were shown with a background of plants, and the same effect, on a larger scale, should be still more attractive.

MR. BROOKS ADAMS, it seems to us, is seriously misleading the public in some of his recent papers on the commercial value of public art. Quoting an estimate, of very doubtful accuracy, that American tourists spend a hundred million dollars abroad every year, he argues that the greater part of this sum goes to enrich the French, Italians and other possessors of beautiful cities and splendid museums, and that, if American cities were as beautiful as Paris, their inhabitants would stay at home, thereby saving their millions for the benefit of their own country. It would be instructive, if it were possible, to ascertain how the money of American tourists in Europe is generally spent, but it is safe to say that the millions that they leave in Paris are exchanged to a much greater extent for clothes and dress-materials than for works of art; and that if Paris had no Louvre, and no boulevards, and no Champs-Elysées, the number of Americans who would go there to buy cheap and pretty clothes, jewelry and fancy goods would not be much diminished. Mr. Adams speaks of England, discerning there signs of exhaustion from a two years' war with a few thousand wretched farmers, and contrasts it with France, which, after defeat in a terrible struggle with the most powerful nation in the world, and the payment of an enormous indemnity, is now the richest nation in Europe, and, as he says, has lent four hundred million dollars in London during the depression of the last year; but, although London has no boulevards, and no very charming public art, more American money is probably spent there than in all the other European cities put together. That a beautiful city like Paris, and, still more, kind and considerate manners, like those of the Parisians, attract visitors and customers, as they have been attracted to Paris for something like two thousand years, is certain; but whether New York can supplant Paris simply through the efforts of an Art Commission remains to be seen.

MR. ADAMS speaks of the Greeks in a cynical manner which will not please artists. According to him, the Greeks were, above all, men of business, carrying their commercial sagacity even into their art. Their temples, as he tells us, were, to a great extent, advertisements for their cities, standing, usually, on hills, where they could be seen to advantage, and built of dazzling white marble, made more brilliant, occasionally, by gilding and colors. Their construction, although costly at the outset, was, in the end, economical, for the trabeated structure needed little or no repair. "It was the most refined," Mr. Adams says, "the most effective and the cheapest form of advertising ever devised, and its success has been commensurate with its deserts. I venture to assert that no investment ever yielded such a large return through so long a period as that made by Pericles on the Acropolis." We think that there are other architectural investments which have yielded a much larger interest than those on the Acropolis, although not, perhaps, for so long a period; but, sagacious as Pericles probably was in business matters, it is hardly credible that he could have looked forward to the curiosity of American tourists for providing an income on his outlay, and the student of history will not forget that, within about thirty years after the completion of the Parthenon, the Athenians had been totally and repeatedly defeated on land and sea, their fleet utterly destroyed, their city entered in triumph by a

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

hostile army, and its fortifications demolished, as a consequence of a war brought on, to a great extent, by the resentment of the other Greeks at their ostentatious magnificence.

WE should be far from wishing to argue against the beautifying of cities, as well as of private habitations, and of the persons who live in them; but we have never yet seen a man or a woman, or a house or a city, adorned with the view solely of attracting attention, that seemed to us beautiful. On the contrary, beauty for the sake of beauty, not for the sake of advertising, is the only kind that has ever been found acceptable to the world, and it is as difficult to believe that Phidias and Ictinus built and carved for the sake of advertising themselves or any one else as it is to comprehend how Pericles should have foreseen a stream of rich tourists, coming to visit the ruins of his temples after they had been devastated by twenty-two centuries of war and neglect. Mr. Adams thinks that the business-like Greeks troubled themselves very little about the inhabitants of their temples, but he does not explain why, in this case, the Athenians should have made their goddess of gold and ivory, instead of painted wood, which would have been much cheaper, and, as the statue was not visible from a distance, equally valuable for advertising purposes. Moreover, if, as he says, "the Greeks were never emotional at a loss," why should one of their most beautiful temples have been put on the uninhabited cliffs of Sunium, where the sailors could see it as they left home, and on their return, but where it was useless for advertising purposes? It is certain that the worship of the ancient gods had lost much of its sincerity at the time when the most splendid temples were raised to them, but it does not follow that these temples were mere pretences, intended only as an excuse for architectural display; and those who are trying to do something to cultivate beauty, and the contentment and happiness which beauty can give, in our domestic and public life, will do best to dismiss at once the idea of advertising, or of attracting tourists, and devote themselves to the only source from which art has ever sprung, the expression in permanent materials of some emotion. The emotions so expressed may vary almost infinitely, from the affectionate cherishing of the memory of friends which fills France with beautiful monuments to the dead, or the feeling of power and responsibility which inspires the Florentine or Genoese palaces, to the unquestioning faith in immortality and angelic guardianship which gives the modern religious art of Russia its singular charm; but without sentiment of some kind there can be no art. With us, the difficulty has been that, instead of expressing our own sentiments, we have copied other people's expression of sentiments with which we have little or no sympathy. No modern, for instance, can enter fully into the passion for the human form, and, perhaps, into the appreciation of the subtleties of outline of which the human form presents the highest example, which were familiar to the Greek, surrounded from infancy with semi-naked people, trained to the most perfect physical development; and modern sculpture of the nude lacks, in consequence, the antique grace. On the other hand, the Greeks, whose sympathies were not cultivated by a religion of love and self-sacrifice, were incapable, probably, of understanding, much more of producing, the marvels of heavenly expression which we find in the works of the early Italian painters, accompanied with very incorrect drawing of the outlines of the body, which the artists regarded as a thing to be despised and kept in subjection. We, perhaps, are as far, at present, from being able to rival the spirituality of Ghirlandajo and Fra Angelico as the purity and elegance of the antique; but there are plenty of characteristic American sentiments which no one else has tried to express, and which we can express better than any one else, if we will only try. No people have a quicker appreciation of truth to nature than the Americans, or are freer from conventional prejudices, and the artist who renders his subject faithfully, in painting or sculpture, is sure of his reward here. Then, for an artist sufficiently developed to see the beauty of his subject, as well as to represent it truthfully, we have the most beautiful models in the world. Nowhere can there be found such variety of unaffected grace in outline and movement, such ease and sincerity, as among our children and young girls; and, for the greatest artists of all, who can perceive and represent what goes on in the hearts of their subjects, we have still left much of the unselfishness and noble aspiration on which the Republic was founded. Any one, therefore, who feels himself capable of adding to the artistic treasures of his country, not as a means of advertising it or himself, but for the sake of representing to others the American traits which he best appreciates, has a wide choice of fields; and if he succeeds in any, he may be sure that his countrymen will not be ungrateful.

THE Boston Museum of Fine-Arts has received, and is arranging in place, a large collection of Classical antiquities, purchased with the aid of friends of the Museum, and including a great number of Greek terra-cottas, with bronzes, marbles and jewelry, and about a hundred Greek vases. Naturally, the task of arranging such a collection is a long one, and it is not impossible that it will not receive its final form until it is placed in the new galleries to be built on the Fenway; but in the meantime, it will be all the more accessible to the multitudes who will wish to see it.

THE Municipal Art League of New York proposes to set up an artistic electric-light standard on one of the "islands" which, following the example of London, are to be established in the middle of crowded streets, to divide the traffic. Apart from the artistic decoration of these islands, they will be of great advantage to the foot-passengers in the crowded streets of New York, and, in a straight street, even if it is comparatively narrow, they form much less of an obstruction than might be supposed. We can very well remember London when there was nothing of the kind there, and to cross Piccadilly, between Regent Street and Bond Street, in the middle of the day, was an undertaking which required time and circumspection, and was very dangerous for children or infirm people. Now, although Piccadilly is no wider than it was then, and is even more crowded, there is no difficulty in crossing it anywhere, and at any time, by taking advantage of the "islands" which are scattered at short intervals through the middle of it, and which not only afford a refuge for the nervous pedestrian half way across the street, but, what is still more important, divide the stream of vehicles, so that the traveller has only to look in one direction for approaching danger, this direction being reversed on each side of the island. What could be done with the surface tracks in Broadway, if islands were put in the middle of the street, we will not undertake to say; but Fifth Avenue, at least, could be furnished with them, and an artistic standard for electric lights in the middle of each might be made to contribute materially to the attraction of the Avenue.

THE newspapers give the interesting piece of information that the members of the Imperial Court of China, feeling, no doubt in view of their recent calamities, the need of being more assiduous in worshipping at the tombs of their ancestors, have resolved to try to raise funds to build a railroad from Pekin to the site of their ancestral tombs, so that, whenever they feel an impulse to commune with the spirits of their fathers, they can take the first train, returning to their duties without unnecessary loss of time. What the spirits of the deceased will say to having the inventions of the "foreign devils" shrieking over their graves is, perhaps, unimportant, in view of the edifying piety of their descendants. A little study of the geography of the affair makes it, however, still more edifying. The ancestors of the reigning house of China were, as every one knows, Mantchu Tartars, and dwelt at Moukden, in Mantchuria, where their graves still remain. Now Moukden is in, or near, the province which Russia practically controls, and not very far from the line of the great Siberian Railway. It is obvious that the Russian railway managers would be glad of a line connecting their road with the great city of Pekin, but what seems to Americans the absurd jealousy of the other Powers would undoubtedly prevent Russia from building any railways in China, outside of Mantchuria; so that the sudden sentimentalism of the Imperial Court comes just at the right moment for providing the desired connection between Pekin and Moukden, without any interference on the part of the Russians. It is evident that the Powers cannot prevent the Chinese from building a railway within their own undisputed territory, for a peaceful and laudable purpose; and if the Russians should be so pleased with this beautiful example of filial affection as to help along the enterprise by advances of money, it is difficult to see how any one can complain. Meanwhile, when Pekin and Moukden are once joined by a railway, it will be very natural for the Chinese to ask the favor of a connection with the Siberian line, and the road from St. Petersburg to Pekin will then be complete.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — IV.

HAVING observed the properties of various sections, which included the section modulus, and having also determined the various formulas for calculating the bending-moment in beams, it is now in sequence to note the application of these several principles.

In order that a beam shall be sufficiently strong to carry the load, the external moments about any point in the beam must be equal to the internal moments. The external moment, as previously explained, is called the "bending-moment," while the internal moment is termed the "resisting-moment"; in this exists the equation $M = M_1$, where M equals the bending-moment and M_1 equals the resisting-moment. The resisting-moment of any beam-section is obtained by multiplying the section modulus of the section by the allowable unit stress, or, as it may be designated, $M_1 = Q\,S$, in which Q equals the section modulus, and S the allowable unit fibre-stress. It is usual

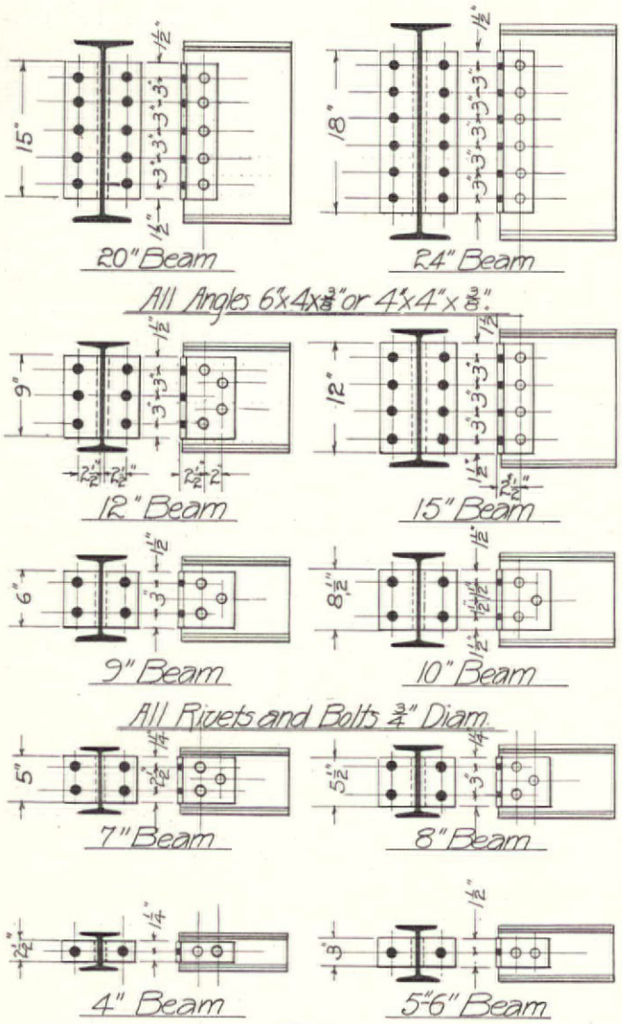

Fig. 20.

in calculating the strength of floor-beams and girders to have first calculated the bending-moment, or M, and to have assumed the allowable unit fibre-stress. From these it is common to figure the section modulus required in the beam section. This is readily done by transforming the former equation to $Q = \frac{M}{S}$; having obtained the value Q, all that is necessary is to refer to any of the tables published by the rolling-mills, and to select therefrom the most economical section that will fill the requirements. Where limiting conditions, such as head-room, or fireproof construction, do not exist, the deepest beam having the least weight and the required section modulus should be adopted.

Example. — A beam having a span of 20 feet supports a uniformly distributed load of 20,000 pounds. Assuming that the safe unit fibre-stress is 18,000 pounds, determine the most economical beam.

Solution: —

$$M = \frac{W\,L}{8}, \text{ or } \frac{20{,}000 \times 20 \times 12}{8} = 600{,}000 \text{ inch-pounds};$$

then Q equals $\frac{M}{S}$, or $600{,}000 \times 18{,}000 = 33\frac{1}{3}$, which is the value required for the section modulus. From almost any steel-mill's hand-book, under the table giving properties of I-beams, it will be noted in the column headed "Section Modulus," that there are two beams that may conveniently be used; one is a 10-inch beam having a section modulus of 35.7, and the other is a 12-inch beam having a section modulus of 36.7; it is evident, however, since the 12-inch beam weighs only $31\frac{1}{2}$ pounds as compared with the 10-inch beam, which weighs 40 pounds, that the 12-inch beam is far preferable — in fact, there is a saving of 25% in weight, and an increase of approximately 3% in strength. Besides, there is much gained in stiffness.

It is the usual practice in steel construction to use an allowable unit fibre-stress of from 15,000 to 20,000 pounds. The usual practice for medium steel, where the beams are subjected to a statical load, is to use an allowable unit fibre-stress of from 15,000 to 16,000 pounds, while if moving loads are apt to occur, or the beams likely to be subjected to sudden stress or shocks, 12,000 pounds per square inch is considered conservative.

In calculating the bending and resisting moments of beams, and equating M with M_1, the bending-moment must always be obtained in inch-pounds, for the result found by multiplying the section modulus by the safe unit fibre-stress gives the resistance of the beams in inch-pounds.

In selecting I-beams for floor-systems, it is the practice never to use a beam less in depth than one twenty-fourth of the span, or never of less depth in inches than one-half the span in feet. By following this rule excessive deflection is avoided, and the deflection that occurs is not sufficient, when the ordinary allowable unit fibre-stresses are used, to produce plaster cracks.

Where head-room is an object, or where architectural considerations prevent the use of beams fulfilling these conditions, the beams must be calculated for a low unit fibre-stress, and the deflection determined by the following table: —

FORMULAS FOR DETERMINING THE MAXIMUM DEFLECTION FOR BEAMS OF UNIFORM SECTION.

Method of Loading.	Deflection in inches.
Fixed at one end, concentrated load at the other.	$\frac{W\,l^3}{3\,E\,I}$
Supported at both ends, concentrated load at centre.	$\frac{W\,l^3}{48\,E\,I}$
Fixed at one end, uniformly loaded.	$\frac{W\,l^3}{8\,E\,I}$
Supported at both ends, uniformly loaded.	$\frac{5\,W\,l^3}{384\,E\,I}$
Fixed at one end and loaded with a right triangular load, the apex at the support.	$\frac{W\,l^3}{15\,E\,I}$
Supported at both ends, loaded with a triangular load apex at the centre.	$\frac{W\,l^3}{60\,E\,I}$

W = load in pounds; l = length in inches; E = 29,000,000; I = moment-of-inertia.

If the deflection found by calculation exceeds one thirty-second of an inch for each foot of span, or one three-hundred-and-sixtieth part of the span, a beam of heavier section should be employed, and thus a lower unit fibre-stress obtained.

In laying out the floor-plan for a building of the skeleton-construction type, all that is necessary is a mere diagrammatic drawing showing the location of the columns and the centre lines of the principal beams and girders, together with the sizes that have been calculated to meet the requirements of the particular case. The connection of the various beams one with the other, and to the girders, and the connection of the girders to the column require careful study. The beams must be so secured to the girders that the connection will carry the maximum reaction at their ends. The connections are made up of two angle-iron clips, which are held to the web of the beam by bolts, and which in turn hold the beam in place to the web of the girder by similar bolts. These connections are so frequently used that they have been standardized by the several steel-mills, as shown in Figure 20. Since the transverse strength of a beam depends directly upon its span, it is evident that standard connections can only be used where the girders have the usual span, and any standard connections which might be adopted are only

[1] Continued from No. 1363, page 45.

secure when the spans of the beams exceed the minimum. The following table, which may be found in almost all of the steel-mill hand-books, gives the minimum spans for which standard

THE MINIMUM SPAN FOR I-BEAMS WHEN STANDARD CONNECTIONS ARE USED.

Size of beam.		Minimum span.	Size of beam.		Minimum span.
Depth.	Weight.	Feet.	Depth.	Weight.	Feet.
20	90	20.5	9	27	10.5
20	80	18.0	9	23½	7.5
20	75	16.5	9	21	9.0
20	65	18.0	8	27	6.0
15	75	16.0	8	22	9.0
15	66⅔	15.0	8	18	7.5
15	60	16.0	7	20	7.0
15	50	15.5	7	15	6.5
15	42	14.0	6	16	7.0
12	55	13 5	6	13	6.5
12	40	12.0	5	13	5.0
12	31½	10.5	5	9¾	4.5
10	40	12.0	4	10	2.5
10	33	11.5	4	8	2.5
10	30	9.0	4	6	2.5

connections can be used. In designing the standard connections an allowable unit shearing-stress of 9,000 pounds was used, while an allowable unit bearing-stress of 18,000 pounds was employed, both values being required in figuring the strength of the bolts in resisting shear, and the bearing of the metal around the bolt-holes in resisting crippling. Where the beam is of a span shorter than the minimum, a special connection must be designed. This can readily be accomplished by calculating the greatest reaction and providing enough bolts to resist the stress.

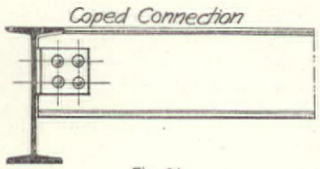

Fig. 21.

Sometimes the connecting-angles are riveted to the beams. In framing I-beams to girders the top flange of the beam may be either flush with the flange of the girder, or dropped below the fillet connecting the flange and web of the girder. The latter practice is usual, as it saves coping the beam as designated in Figure 21. The expense of cutting away the upper flange of the beam to fit the flange of the girder adds considerably to the cost of the work, and this method of framing is only employed where architectural considerations require that the beam shall be flush upon the upper flanges. It is the practice in the erection of the work in the field — that is, the assembling of the beams making up the floor-system, for the erector to place the beams in position, putting one or two bolts in a connection and proceeding over the entire work in this manner, going over each connection finally, and putting in all the bolts. In order that this work may be done properly requires rigid inspection, for many bolts are left out entirely, and the majority of those in place are seldom bolted tight. The inspector in going over this work should mark each connection that is improperly bolted with a chisel, chalk and paint being inadequate, as unscrupulous workmen are liable to erase such marks rather than bolt the connection properly.

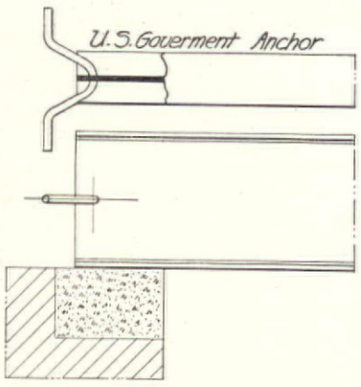

Fig. 22.

The tail-end of each steel floor-beam, that is, the end which has its bearing upon the wall, should be securely anchored into the wall, and each beam should have a sufficient bearing upon the masonry. The common form of anchor used for the tail-end of beams is what is known as the United States Government anchor, which consists of a piece of ¾-inch round iron, bent to the form shown in Figure 22. This anchor is placed through the end of the web of the I-beam, and is securely built into the stone or brickwork. Where two beams are placed opposite to each other on a partition-wall, they are sometimes anchored as shown in Figure 23 by means of a wrought-iron strap consisting of a piece of 2″ x ¼″ bar, punched on the ends, and bolted to the webs of each beam. The difficulty in the use of this system of anchorage upon a

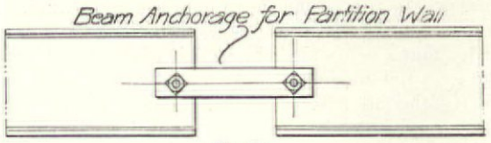

Fig. 23.

partition-wall lies in the fact that it is practically impossible to construct a building so accurately or to obtain the steelwork punched to such a nicety that the straps can be made in the shop — the hole in one end of them must necessarily be punched or drilled in the field. While this means of anchoring two systems of floor-beams bearing upon a partition-wall is excellent, the practical objections are difficult to overcome, and the Government anchor is usually resorted to.

Where the ends of steel beams rest upon a wall they should have from a 6-inch to 12-inch bearing, the usual bearings for the different sized beams being as follows: —

Under	6 inches	6-inch bearing.
Over 6 inches and under 8 inches		8-inch bearing.
Over 8 inches and under 12 inches		10-inch bearing.
Greater than	12 inches	12-inch bearing.

In any case the bearing of the steel beams upon the wall should not produce a greater stress per square inch of bearing-surface than is given by the following table: —

SAFE BEARING PER SQUARE INCH FOR BRICKWORK AND MASONRY.

Brickwork laid in cement-mortar	200 pounds.
Brickwork laid in lime and cement-mortar	150 pounds.
Brickwork laid in lime-mortar	100 pounds.
Concrete, of the best Portland-cement	150 pounds.
Rubble masonry in lime-mortar	80 pounds.
Rubble masonry in Portland-cement mortar	150 pounds.

The brickwork in the above table is assumed to be of first-class workmanship, well bonded, and of hard, well-formed burned brick. Where the bearing of the bottom flange is likely to produce a pressure greater than those given in the above tables, either steel bearing-plates or stone templates should be used upon the wall to distribute the pressure and in order to prevent crushing. When stone templates are used to distribute the pressure, they may be subjected to a bearing-pressure from the lower flange of the steel beams of at least 500 pounds per square inch, provided the thickness of the template is not less than 8 inches. Where bearing-plates of steel are used underneath the ends of the beams, the length and breadth of the plate should be determined from the safe bearing-pressure of the brickwork or masonry, and the thickness calculated by the following formula: —

$$t = .87\,(l - w)\sqrt{\frac{W}{S w_1 l}}$$

in which t equals the thickness of the plate in inches, l the length of the bearing-plate at right angles to the length of the beam, w equals the flange-width of the beam in inches; W equals the reaction at the point of support in pounds; S equals the allowable unit stress in the plate; w_1 equals the width of the plate, or the dimension parallel with the length of the beam — that is, the bearing on the wall in inches.

Example. — The end of a 20-inch girder of I-beam section, and having a flange-width of 6 inches, has a 12-inch bearing upon a wall built of good hard bricks laid in cement-mortar, the reaction at the end amounting to 25,000 pounds. It is required to determine the size and thickness of the bearing-plate.

Solution. — From the table given above it is ascertained that good brickwork in Portland-cement mortar will support 200 pounds per square inch; since the bearing-length of the plate will be 12 inches, the allowable load for each inch in the width of the plate will be 12×200, or 2,400 pounds; dividing 25,000 pounds by 2,400 pounds it is found that the width or length of the bearing-plate perpendicular to the axis of the girder is equal to $10\frac{1}{2}$ inches; the size of the plate has then been found to be $12'' \times 10\frac{1}{2}''$; and it is required to determine the thickness. Substituting in the formula, when S, or the safe allowable fibre-stress in the plate equals 16,000, it is found that

$$t = .87\,(10\tfrac{1}{2} - 6)\sqrt{\frac{25{,}000}{16{,}000 \times 12 \times 10.5}}$$

or .605, which is practically a $\frac{5}{8}$-inch plate. The following table gives the usual size and thickness of bearing-plates for the different sized beams and the safe pressure at the end of the beams in tons that they will carry: —

TABLE OF STANDARD BEARING-PLATES FOR I-BEAMS GIVING THE SAFE END-REACTION AT THE END OF THE BEAM IN TONS, WHEN THE SAFE-BEARING ON THE MASONRY EQUALS 100 POUNDS PER SQUARE INCH.

Size of beam.	Size of standard plates for templates.			Safe end-reaction.
	Length.	Width.	Thickness.	
20″	12″	16″	$\frac{3}{8}$″	9.6
15″	12″	12″	$\frac{3}{8}$″	7.2
12″	10″	10″	$\frac{3}{8}$″	5.0
10″	10″	8″	$\frac{3}{8}$″	4.0
8″	8″	8″	$\frac{3}{8}$″	3.2
6″	6″	8″	$\frac{3}{8}$″	2.4

The size of a stone template depends upon the allowable pressure on the brickwork. The template should never project in any direction beyond the bearing-plate or flange of the beam more than three-fourths of the thickness of the stone.

The steel beams forming the main support of a fireproof-floor system are tied together laterally by means of tie-rods. These tie-rods are from $\frac{5}{8}$ inch to $\frac{7}{8}$ inch in diameter, and are placed from 4 to 6 feet from centre to centre. There are several empirical rules for the spacing of these rods; one is, to make the distance from centre to centre of rods not greater than twenty times the flange-width; another, which is not so reasonable, that the distance between the rods should not be greater than eight times the depth of the beam. Since the lateral resistance of a beam does not depend upon the depth, to any extent, it would seem that the first rule is the most consistent. The tie-rods should be placed as nearly coincident with the centre of the thrust of the arch as possible, though where segmental arches are used, the tie-rods should not project below the crown of the arch; ordinarily they are placed below the centre-line of the beam, and often very close to the bottom flange. In any case the steel rods must come within the fireproofing material, otherwise they will be exposed to the heat of a possible conflagration, and the principal purpose of their instalment abrogated. Usually the thrusts of the arches in adjacent bays or panels counterbalance each other, and tie-rods are only really required in one panel to take the thrust of the end arch from the walls, or from the beam adjacent to the walls. They are, however, necessary to prevent lateral deflection of the beams in case of fire and during construction.

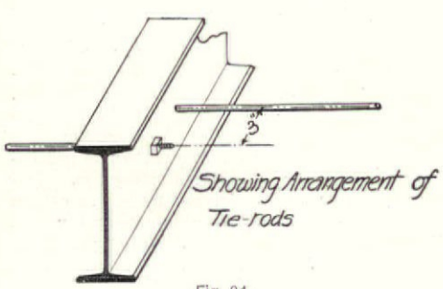

Fig. 24.

Since the tie-rods secure each beam to the other laterally, it is necessary to provide holes in the webs for the rod attached to the beam on the one side, and also for the rod attached to the beam on the other side. These holes should not be farther apart than 3 inches, as designated in Figure 24.

Where brick arches are used the horizontal thrust of the arch is readily found by the formula

$$p = \frac{1.5\ W L^2}{r}$$

in which p equals the thrust of the arch in pounds for each lineal foot, W equals the load in pounds per square foot of floor-surface; L equals the distance in feet between beams, or the span of the arch, and r equals the rise of the arch in inches. If the I-beam has a sufficient lateral resistance to bending to take up this thrust, no tie-rods need be used. The calculation for the thrusts may be applied in determining the distance apart of the tie-rods. A beam supported laterally by a number of tie-rods is semi-continuous, and the distance between the supports may be determined for I-beams and channels by the following formulas: —

$$L = \sqrt{\frac{C A w}{p}}$$

in which L equals the distance between tie-rods in feet; C is the constant, which for I-beams is 1,300, and for channels is 1,650; A is the sectional area of the beams in square inches; w the width of the flange in inches, and p is the lateral pressure in pounds per lineal foot of the arch.

Example. — A brick arch having a span of 4 feet, and a rise of 6 inches, is supported upon 12-inch I-beams having a sectional area of 16 square inches; provided the load upon the floor is 300 pounds per square foot, what distance apart should the tie-rods be spaced?

Solution. — The horizontal thrust of the brick arch per lineal foot, or p, equals $\frac{1.5 \times 300 \times 4 \times 4}{6}$, or 1,200 pounds. Then substituting in the formula $L = \sqrt{\frac{1{,}300\ A W}{p}}$, it becomes $L = \sqrt{\frac{1{,}300 \times 16 \times 6}{1{,}200}}$, or 10.2 feet, which is the desired result, or distance between centres of tie-rods.

It is sometimes necessary to proportion steel beams to withstand the effects of a suddenly applied load; such a condition often exists where the beams support the mechanism at the head of an elevator-shaft. It is considered by the best practice that a load suddenly applied produces a strain upon a beam or girder equal to twice the amount that the same load would produce if it were static. That is, a suddenly applied load should only be one-half as great as the safe statical load. Where the load falls some distance upon the beam the stress produced in the beam is very great, due to the impact, and the usual method employed to determine the resistance of the beam under such a severe condition is to equate the effect of the falling load to the effect of a statical load applied at the same position on the beam, and from these data determine the required section modulus. The formula used for determining the amount of the statical load that would produce the same effect as a certain falling load is as follows: —

$$W s = W\left(1 + \sqrt{\frac{2\,m\,h}{d}} + 1\right)$$

in which $W s$ equals the statical load that would produce an equivalent effect; W the falling load; h the height in inches through which the load falls; d the deflection of the beam, in inches, that would be produced by the load W if at rest, while m is obtained from the following formula: —

$$m = \frac{1}{1 + \frac{L}{2.06\,W}}$$

in which L equals the weight of the steel beam and the entire dead load which it carries.

It is often necessary in building-construction to use several I-beams side by side to carry a load so great that one beam would be insufficient. Such girders are especially used for lintels for supporting brickwork over openings. Where there are no openings above the girder, good brickwork arches itself, and the load upon the girder is triangular in shape, the altitude of the triangle being taken at one-third the span. Where two or more I-beams are used together and are subjected to the same load, they should be tied together at intervals of from 6 to 8 feet, and separators should always be provided at the ends of such girder, and also wherever a concentrated load is located. Where a girder composed of two I-beams is used in floor-construction, and the floor-beams are framed into it, care must be taken to see that the connections do not interfere with the separators, and, wherever possible, separators should be placed adjacent to the connections. It is customary in making such connections to bolt the angles attached to the beam on the one side to the web of the one beam, while the angles attached to the beam on the other side are bolted to the web of that beam, — that is, the bolts securing the connections to the girder do not extend through the girder. It is necessary, therefore, that a girder composed of two I-beams, and required to support the ends of floor-beams, should be shipped in pieces and put in place in the field.

M. M. Sloan.

[To be continued.]

A Tripolitan petrified Forest. — Describing his journey in the forbidden desert in the hinterland of Tripoli, Mr. Dodson, who has recently returned to England, says that one of the most notable things on the journey to Murzuk was the great petrified forest, which his party passed through. For ten hours they travelled across an area of petrified trees, varying in circumference from seven feet to a few inches. Every branch of this forest was, of course, lying prone, and this, together with the presence of marine shells, showed that this part of the Great Sahara had at one time been submerged. — *Exchange.*

OWNER'S RESPONSIBILITY FOR PAYMENT OF PROVISIONAL SUMS.

IN the Court of Appeal on the 17th inst. the appeal case Hobbs *vs.* Turner was heard. According to the report in the *Times*, the plaintiff, who was a metalworker, sued the defendant, a building-owner, for £27 10*s.*, for metalwork supplied for a house which the defendant was having built for him by a builder under the supervision of Mr. J. L. Williams as architect. The contract under which the house was being built was made in September, 1898, and was in the form settled and issued by the Royal Institute of British Architects. By the contract the builder, in consideration of a sum of £4,700, agreed, upon and subject to the conditions in the schedule to the contract, to execute and complete the works described in the specification. Payment for the work was to be made by instalments as the work progressed, according to the certificate of the architect. Clause 28 of the contract, so far as material, was as follows: "The provisional sums mentioned in the specification for materials to be supplied or for work to be performed by special artists or tradesmen, or for other works or fittings to the building, shall be paid and expended at such times and in such amounts and to and in favor of such persons as the architect shall direct, and sums so expended shall be payable by the contractor without discount or deduction or . . . by the employer to the said artists or tradesmen. The value of works which are executed by the contractor in respect of provisional sums, or in additional works, shall be ascertained as provided by Clause 13. At the settlement of the accounts the amount paid by the contractor to the said artists or tradesmen, and the said value of such works executed by the contractor, shall be set against all such provisional sums or any sum provided for additional works, and the balance shall be added to or deducted from the contract sum."

The specification contained this clause: "Provide and fix iron balcony-railings to design (allow £20 for this, irrespective of carriage, fixing and profit)." It was not suggested that there was anything in the specification to alter the legal rights of the parties. The architect selected the plaintiff as the person to supply the ironwork for the balconies, and the builder asked the plaintiff to send designs to the architect, who rejected them, and sent the plaintiff his own designs; and the builder having given measurements and quantities, the ironwork was sent to him (the builder) and the goods were invoiced and debited to him. Later on, in November, 1899, the builder wrote to the plaintiff asking him to send him his account, and he did so; but on December 9 the builder wrote saying that the architect would certify the amount direct to the building-owner (the defendant), and on December 14, 1899, the architect sent to the plaintiff a certificate addressed to the defendant certifying that the plaintiff was entitled to be paid £27 10*s.* for the ironwork. This certificate the plaintiff sent to the defendant, who kept it, making no reply. After this the plaintiff sent two or three times to the defendant for the money, of which the defendant took no notice. In October, 1900, when the plaintiff's solicitor wrote for payment, the defendant repudiated liability. The defendant alleged that he had a claim against the builder for bad work. Mr. Justice Kennedy gave judgment in favor of the plaintiff. The defendant appealed.

The Court dismissed the appeal.

The Master of the Rolls said that, in his opinion, the appeal should be dismissed. The contract was one which was not an unusual one at the present time, namely, the builder undertook to do certain portions of the work, and as to the other portions of the work provisional sums were specified. The specification contained this clause: "Provide and fix iron balcony-railings to design (allow £20 for this, irrespective of carriage, fixing and profit)." That threw them back upon the original central undertaking of the builder contained in the contract and the conditions. In consideration of the sum of £4,700 the builder agreed to execute and complete, subject to the conditions in the schedule to the contract, the works described in the specification. In the conditions and specification they found how that lump sum was to be distributed. They found that the builder was not necessarily to execute the whole of the work, but the building-owner might get other persons to do certain parts of the work, and as against the builder certain fixed sums only were to be paid out of the lump sum to those persons for that particular class of work. It was good sense that a sum should be fixed for each class of work which was not to be executed by the builder, but by some tradesman or artist designated by the architect. The building-owner — the defendant — had a discretion as to the person by whom this class of work was to be done, and he might agree to pay him any sum he pleased, but he could only allow as against the builder the fixed sum for each class of work. That being so, Clause 28 of the conditions seemed to him to contemplate payment for this class of work being made either by the builder or by the building-owner, and the last part was based on the hypothesis that part of the work might be done by the builder and part not done by him, and where any such work was not done by the builder the building-owner would be entitled to hold back the amount specified for that work. This clause was obviously framed upon the footing that the building-owner was liable for this particular class of work. In his opinion, when one looked at the whole of the contract taken together, and not relying upon any one particular clause, the proper inference as regarded this particular class of work was that it was intended that the building-owner, and not the builder, should be the principal. If the builder entered into a contract for any of this class of work he might make himself liable to the tradesman or artist; but, as he was acting under the general scope of the contract, he would be acting as the agent of the building-owner and would create privity of contract between the building-owner and the tradesman or artist. That could only be got rid of by the tradesman or artist contracting with the builder in such a way as to debar himself from resorting to the building-owner. Nothing of that kind occurred here. What happened was that the plaintiff was put into relation with the defendant through the architect, and, though this was not clear, he understood that the order was given to the plaintiff by the architect. It was true that the invoice was sent to the builder, but the architect gave a certificate against the defendant, and not against the builder, and sent it to the defendant. His lordship did not intend to say anything about the point as to estoppel, nor was it necessary to decide whether, under Clause 28 of the conditions, the architect had authority to determine who was to pay as well as to whom payment should be made. It seemed to him, looking at the contract as a whole, that the initial liability of the defendant — the building-owner — in respect of this class of work was established, and that all the parties dealt upon that footing. The judgment was, therefore, right.

Lord Justice Romer agreed.

Lord Justice Mathew was of the same opinion. This was a question of fact which had been properly decided by the learned judge. — *The Architect.*

BOOKS AND PAPERS.

IF the English-speaking race remains ignorant upon art, it cannot be the fault of the publishers of books, nor of the dealers in pictures. Book succeeds book, just as exhibition succeeds exhibition: They come, they come, *immer, immer mehr*, and at prices ranging from 10 guineas to 12 pence. Does this work for good as regards the culture of the people? Can a shilling book compass enough information to be of any real value, when we consider that it contains no less than eight illustrations, is well printed on good paper and neatly bound in cloth? This question may be answered by a short review of these "miniature books"[1] upon painters.

Of course, the possibility of publishing these and even the more expensive "*Great Masters*" series at 5*s.* or 7*s.* 6*d.* must depend upon the fact that the authors of the voluminous 5 or 10 guinea books are willing to condense their works, and boil them down to 50 or 60 pages of a post 8vo volume. Also as a passport to efficient work, we have Mr. Williamson as an editor to the series. Naturally, some of the books are better than others, and Mr. Williamson's "*Fra Angelico*" leaves little to be desired as a handbook to San Marco, or as a simple book of reference. Of course it is not sufficient for the student, but the author gives a list of books upon the subject which will enable him to learn more. There is also a list of Fra Angelico's principal pictures scattered over Europe, and a very useful chronological table of the principal pictures of the painter's working years. These added to a clearly-written and concise history of the master's life is not a bad shilling's worth, and must, we think, work for good as regards culture, just as "penny poets" help the laboring population to a little enjoyment in a more or less uninteresting life. The present writer has seen a penny "*Shelley*" lying by the side of a carpet-factory girl to entertain her during the dinner hour. "Yes, she did love Shelley," she replied to a question. What matters it whether she understood him or not? The music helped her through many a dull hour, as it does the rest of us.

Mr. Williamson criticises Fra Angelico's art as well as his religion. He used art "as a means of imparting religious instruction," and thus gave it "its greatest dignity." He also "employed the talents which God had given him" to "their best advantage." "He knew that to be a saint was more in the eyes of God than to be an artist," and so, "the unity between these two phases of character was not impossible, as some persons have thought." Possibly, many a modern painter has felt this, and used as much fervor and prayer during his work as the great Dominican, only in a less obvious manner. Mr. Williamson suggests that the great "Crucifixion" at San Marco refutes the opinion that the painter ignored the study of the nude. On the contrary, he argues, Fra Angelico painted all that he touched with exquisite truth — flowers, dancing-figures, expressions of feeling as depicted upon the human face, little vistas of landscape — all was handled with loving care and exquisite sentiment. Perhaps the best example of the harmony of the Saint and the Painter may be seen in the dainty and exquisite dance of the angels in the "Last Judgment" in the Accademia at Florence.

In Mr. Staley's "*Watteau*," much remains to be desired, and notably, correction of French quotations and words. "Gave upon the market-place" is scarcely classic English; and the following may be cited as curious blunders due to the careless correction of proofs, or the printer. Audran living "during the old age of Louis IV." The "*Chateaux de Merdon*," for "*Chateau de Merdun*"; "*Le défait de Goltath*"; "*Abigail que apport les vivres*"; "*Ils n'ont pas l'air decroire à leur bonheur*"; and last, not least, the frequent use of

[1] "*Fra Angelico*," by George C. Williamson; "*Watteau*," by Edgecumbe Staley; "*Romney*," by Rowley Cleeve. Bell's Miniature Series of Painters. 1*s.* London. 1901. "*The Art of Illustration*," by H. Blackburn, revised by J. S. Eland. New Edition, 98 Illustrations, with a chapter upon Colored Illustration. John Grant, Edinburgh.

"*coiffeur*" for *coiffure*. The ladies wore *coiffeurs* on their heads! and we are told of the "beautiful *coiffeurs*" of the period! Why, too, need the author speak of "details of *mode* and texture," and "interesting *toilettes*"; language which he borrows from the drapers' and dressmakers' lists.

In spite of these blemishes, and a certain want of sympathy for Watteau, the book is a pretty little volume well illustrated, indeed the illustrations are the best part of the work; for although but small, 3″ x 4″, they give a very fair idea of the grace and elegance of the painter's compositions; they remind one of much of the printed Worcester, the makers of which reproduced many of Watteau's engravings on their china. Among the list of chief books upon Watteau the author gives Walter Pater's "*Imaginary Portraits*";[1] but Mr. Staley has not imbibed the poetic and sympathetic tone of the Oxford Don's charming sketch of Watteau and his pupil, Jean Baptiste Pater.

The Romney volume also contains some pretty illustrations, but the letterpress consists chiefly of the life of Lady Hamilton. This is written with much more detail than is usual or necessary, with the result that the volume cannot be given to the young; and why we need know the details of the lady's love affairs in order to account for the fascination of her face seems quite unnecessary.

Mr. Cleeve considers Romney a better draughtsman than either Reynolds or Gainsborough, but as colorists he places the latter first of the three — indeed with our author, the President fares badly, and quite takes a back seat. No doubt there is great charm in the coloring of Gainsborough, but it has not the pureness of tone of a good Reynolds; and when we consider his work from the point-of-view of strength, he does not approach Reynolds. Romney, too, was a fine colorist; his handling of a white muslin gown is unrivalled, but we surely should find no difficulty in putting Reynolds as the first of British painters if we saw his best portraits and the best of Gainsborough's and Romney's side by side with those of Rubens, Velasquez and Rembrandt. The President would stand the strain; but it is more than doubtful whether the work of his rivals would, even at their best. The chief beauty of Romney's work is its directness; its bad qualities are thinness of tone, and sometimes an effect of careless hurry. But there is no doubt that there is a marvellous charm about the mere *technique* of such a work as "Mrs. Mark Currie" (National Gallery, London), and Romney was more fortunate than his rivals in the fashions, which had become simpler, more easy, and, above all, the hair was dressed far more becomingly.

The new edition of Mr. Blackburn's book is brought up to date, and for those engaged in drawing for the press is invaluable, both in its "hints" and instructions, and for its illustrations. It describes all the modern processes, and gives examples of reproductions of most of them. It is well printed, and, barring its weight, which is inevitable, is altogether a charming as well as a most useful book for draughtsmen.

ILLUSTRATIONS

[*Contributors of drawings are requested to send also plans and a full and adequate description of the buildings, including a statement of cost.*]

NOTES & CLIPPINGS

ANDREW CARNEGIE'S GIFTS. — The *N. Y. Times* makes the following tabulation of Mr. Carnegie's public benefactions: Carnegie, Andrew, New York, gifts for a technical school at Pittsburgh, Pa., $2,000,000, with promised endowment of at least $25,000,000; to the Government of the United States, to establish in Washington a university for higher education, $10,000,000; to the Carnegie Institute, Pittsburgh, $1,000,000; to Cooper Union, New York, $300,000; Upper Iowa University, Fayette, Iowa, $225,000; to Bellevue Medical College, New York, $76,000; to Carnegie Laboratory, New York, $50,000; to Aurora (Ill.) College, $50,000; New York Educational Alliance, $2,500. Besides these gifts by Mr. Carnegie there remain his gifts to public libraries. In the *Library Journal* for January of this year is given a table of such gifts which shows the immense total of $13,813,000. This sum was distributed among 153 places in thirty-three States, Porto Rico, Canada, and British Columbia, the largest individual items being $5,000,000 for branch libraries in New York City, $1,000,000 to St. Louis for the same purpose, and a like sum for the endowment of the Carnegie libraries of Bradford, Duquesne, and Homestead, in Pennsylvania. The record is as follows: —

Aberdeen, S. D.	$15,000	Macon, Ga.	$20,000
Akron, Ohio	70,000	Madison, Ind.	20,000
Alameda, Cal.	35,000	Madison, Wis.	75,000
Atlanta, Ga. (additional)	20,000	Mankato, Minn.	40,000
Aurora, Ill.	50,000	Marion, Ind.	50,000
Austin, Minn.	12,000	Mattoon, Ill.	20,000
Beloit, Wis.	25,000	Miles City, Mon.	10,000
Bloomington, Ill.	15,000	Moline, Ill.	37,000
Braddock, Duquesne, and Homestead Carnegie Libraries, Pa.	1,000,000	Montclair, N. J.	30,000
		Montgomery, Ala.	50,000
Burlington, Vt.	50,000	Montreal, Can.	150,000
Canandaigua, N. Y.	10,000	Mount Vernon, N. Y.	35,000
Cañon City, Col.	10,000	Muncie, Ind.	50,000
Canton, N. Y.	30,000	Nashville, Tenn.	100,000
Canton, Ohio	50,000	Neenah, Wis.	10,000
Carbondale, Pa.	25,000	New Rochelle, N. Y.	25,000
Carrollton, Ill.	10,000	New York City	5,000,000
Catskill, N. Y.	20,000	New York Press Club	5,000
Charleston, Ill.	18,000	Niagara Falls, N. Y.	50,000
Cedar Rapids, Ia.	75,000	Norristown, Pa.	50,000
Centralia, Ill.	15,000	Norfolk, Va.	50,000
Charlotte, N. C.	25,000	Norwalk, Conn.	20,000
Charlottesville, W. Va.	20,000	Nyack, N. Y.	15,000
Chatham, N. Y.	15,000	Oneida, N. Y.	11,000
Clinton, Ia.	30,000	Ottawa, Can.	100,000
Clinton, Mass.	25,000	Oyster Bay, N. Y.	1,000
Cohoes, N. Y.	25,000	Paducah, Ky.	35,000
Collingwood, Ontario, Can.	10,000	Pekin, Ill. (additional)	5,000
Conneaut, Ohio	100,000	Pembroke, Ontario, Can.	10,000
Cornell College, Ia.	40,000	Pensacola, Fla.	15,000
Covington, Ky. (additional)	35,000	Perth Amboy, N. J.	20,000
Crawfordsville, Md.	25,000	Peru, Ind.	25,000
Cumberland, Md.	25,000	Phœnixville, Pa.	20,000
Danville, Ill.	40,000	Port Jarvis, N. Y.	30,000
Davenport, Ia.	25,000	Portland, Ind.	15,000
Decatur, Ill.	60,000	Portsmouth, Ohio	50,000
Detroit, Mich.	750,000	Revere, Mass.	20,000
Elkhart, Ind.	35,000	Racine, Wis.	50,000

Freeport, Ill.	30,000	St. Cloud, Minn.	25,000
Fresno, Cal.	30,000	St. Johns, N. F.	50,000
Galesburg, Ill.	50,000	St. Joseph, Mo.	25,000
Gloversville, N. Y.	25,000	St. Louis, Mo.	1,000,000
Goshen, Ind.	25,000	San Francisco, Cal.	750,000
Grand Junction, Col.	3,000	San José, Cal.	50,000
Great Falls, Mon.	30,000	San Juan, P. R.	100,000
Green Bay, Wis.	25,000	Sault Ste. Marie, Mich.	30,000
Greenville, Ohio	25,000	Schenectady, N. Y.	50,000
Griffin's Corners, N. Y.	5,000	Seaboard Air Line (travelling libraries).	1,000
Grossdale, Ill.	35,000	Seattle, Wash.	200,000
Guthrie, O. T.	20,000	Sharon, Pa.	25,000
Hawarden, Ia.	5,000	Sheboygan, Wis.	25,000
Hempstead, N. Y.	25,000	Sioux Falls, S. D.	25,000
Henderson, Ky.	25,000	South Omaha, Neb.	60,000
Iron Mountain, Mich.	17,500	Springfield, Ill.	75,000
Ishpeming, Mich.	20,000	Staten Island (N. Y.) Academy	500
Islip, N. Y.	10,000	Stillwater, Minn.	25,000
Jackson, Mich.	70,000	Stratford, Manitoba, Can.	12,000
Jackson, Tenn.	30,000	Superior, Wis.	50,000
Jacksonville, Ill.	40,000	Syracuse, N. Y.	260,000
Janesville, Wis.	30,000	Tacoma, Wash.	50,000
Johnstown, N. Y.	20,000	Upper Iowa University, Ia.	25,000
Joplin, Mo.	40,000	Valley City, N. D.	15,000
Kalispell, Mon.	10,000	Vancouver, B. C.	50,000
Kansas City, Mo.	75,000	Wabash, Ind.	20,000
Kent, Ohio	10,000	Walpole, Mass.	15,000
Lewanee, Ill.	50,000	Washington, Ind.	20,000
Lake Charles, Ia.	10,000	Waukegan, Ill.	25,000
Lawrence, Kan.	25,000	Wheeling, W. Va.	75,000
Leadville, Col.	100,000	Windsor, Ontaria, Can.	20,000
Lewiston, Me.	50,000	Winnepeg, Manitoba, Can.	100,000
Lincoln, Ill.	25,000	Yonkers, N. Y.	50,000
Los Gatos, Cal.	10,000		
McKee's Rocks, Pa.	20,000	Total	$13,813,000

In addition, Mr. Carnegie's gifts for library purposes in Great Britain are recorded as reaching a total of £179,500, or over $800,000. These were distributed to eight places, of which all but one were in Scotland, the record being as follows: —

Annan, Dumfriesshire, Scotland.	£3,000	Glasgow, Scotland.	£105,000
Coabridge, Lanark, Scotland	15,000	Larbert, Stirling, Scotland.	3,000
Dalkeith, Scotland.	4,000	Rutherglen, Lanark, Scotland.	7,500
Dundee, Scotland.	37,000	Waterford, Ireland.	5,000
		Total	£179,500

ALUMINO-THERMIC WELDING. — By a new modification of the Goldschmidt process of alumino-thermic welding and casting, skilled labor is

not necessary, and an ordinary workman can easily effect a good weld. The time is also shortened. The "thermit" mixture (of which one kilogramme yields 450 grammes of molten iron) is placed in a crucible made of iron plate lined with refractory material, mounted on a substantial tripod and closed at the bottom with one or more small iron plates, according to the quantity of "thermit" used. The "thermit" is covered with a layer of kindling or priming mixture, and an iron plate having a central hole, through which the charge can be ignited by means of a fuse, is placed over the whole. The crucible thus prepared is placed with its tap-hole immediately above the gate of a refractory mould built around the ends of the two rails to be jointed, which are so clamped together that the surfaces to be welded are pressed against each other. When all is ready, the charge is ignited, and in a few seconds the contents of the crucible should become fluid, and melting away the supporting iron plates, should flow into the mould and make the required joint. In this process it is the molten iron which first enters the mould, and the molten corundum slag floating on the top passes out last, instead of first as in the older teeming process. The method lends itself well to the jointing of rails already laid, and ensures a sound electrical contact; it is of no use, however, for rails of which the ends are worn, as it does not assist in checking the hammering of the wheels on the rails. The process cannot well be applied to the welding of tubes, as the hot metal is liable to melt its way through the tube at first contact; it is, however, very suitable for the repair of broken shafts or axles, and is especially recommended for use on board ship, as the appliances required are exceedingly simple and convenient. — *N. Y. Evening Post.*

New York's most valuable Buildings. — The following list includes many, but probably not all, of the buildings in New York City that are assessed this year at a valuation of a million or more dollars: —

OFFICE-BUILDINGS, 1902.

Produce Exchange	$3,000,000	Astor Building	$1,500,000
Bowling Green Building	2,500,000	A. L. Stevens Building	1,175,000
Washington Building	1,560,000	American Exchange National Bank	1,000,000
Empire Building	2,400,000	National Bank of Commerce	2,000,000
Standard Oil Building	2,250,000	Trinity Building	1,000,000
Exchange Court	2,250,000	Boreel Building	1,600,000
Consolidated Exchange	1,300,000	Havemeyer Building	1,000,000
Union Trust	1,600,000	Western Union Building	1,400,000
Wilks Building	1,150,000	National Park Bank Building	1,100,000
Stock Exchange Building	2,100,000	St. Paul Building	1,200,000
Commercial Cable Building	1,200,000	Park Row Building	2,400,000
Johnston Building	1,800,000	Potter Building	1,150,000
Lord's Court Building	1,150,000	American Tract Society Building	1,000,000
Mills Building	2,100,000	Pulitzer Building	1,500,000
Broad Exchange Building	3,250,000	Postal Telegraph Building	1,350,000
Drexel Building	1,200,000	Mutual R. F. Association Building	1,050,000
Atlantic Building	1,800,000	Stewart Building	2,000,000
National City Bank (Custom-house)	2,800,000	Central National Bank Building	1,200,000
Manhattan Company Bank	1,800,000		
United Bank	1,450,000		
American Surety Building	2,000,000		
Hanover National Bank Building	1,300,000		

INSURANCE-BUILDINGS, 1902.

Manhattan Life	$1,500,000	Washington Life	$1,700,000
Mutual Life Company	4,700,000	New York Life Company	3,000,000
Equitable Life	6,350,000		

HOTELS AND APARTMENT-HOUSES, 1902.

Astor House	$2,000,000	Imperial	$1,250,000
Fifth Avenue Hotel	3,000,000	Sherry's	1,100,000
Waldorf-Astoria	6,000,000		

THEATRES, 1902.

Metropolitan Opera-house	$1,500,000

FIFTH-AVENUE RESIDENCES, 1902.

756 — Cornelius Vanderbilt, estate	$1,550,000

Difficulty of disposing of Italian Family Art-treasures. — The difficulty experienced by any Italian who wishes to dispose of one of his family art-treasures has been much discussed of late, but we make no excuse for quoting from *The Athenæum* some notes on the subject just contributed to that journal by its correspondent in Rome. This gentleman is Professor Rodolfo Lanciani, whose authority in matters of art and archæology is widely recognized both in Europe and in the United States. He writes: "Commendatore Carlo Fiorilli, the genial Director-General of Antiquities, has published a report on the *attività amministrativa* of his department from January, 1900, to June, 1901. The volume is full of useful information as regards the safe keeping of antique monuments, the results of excavations, the new acquisitions of museums and galleries, etc. As regards the case against Prince Chigi on account of the famous Botticelli "Madonna," Commendatore Fiorilli's report says (page 164): In June, 1899, Prince Don Mario Chigi sold, for 315,000 lire, to Edmond Desprez, of the Colnaghi house of London, by the arrangement of Signor Enrico Pardo, the famous picture of Botticelli, 'La Vergine col Bambino benedicente l'Offerta d' un Angelo.' In announcing the sale to the Ministry of Public Instruction, Prince Chigi declared the purchaser to be a certain Lazzaro Papi, no trace of whom, it seems, could be found. The affair was brought before the first section of the Penal Court on October 24, 1900, and Prince Chigi and Desprez were condemned to pay a fine of 315,000 lire, the value of the lost picture. The Court of Appeal revised this judgment on February 28, 1901, reducing the fine to 2,000 lire, which was further reduced to a nominal sum of 200 lire, in consequence of a royal amnesty for offences of this nature granted on November 11, 1900. From this sentence both parties again appealed to the Supreme Court, the decision of which has just been published. It is in favor of a new trial before the Court of Appeal of Perugia. I am told, however, that the wording of the decree is such as to leave the condemnation of Prince Chigi and Edmond Desprez to the full penalty of the law a foregone conclusion. From the same official publication I learn that the Princess Barberini-Sacchetti has been reported to the Public Prosecutor for having sold to the Louvre Museum, without proper license, the famous ivory diptych of Constantine, and the not less famous Siculo-Arab vase 'ageminated' in silver. She is also charged with selling to an unknown person the most precious codex of the Barberini Library. The tapestries belonging to the same family, and marked with the coat-of-arms of Pope Urban VIII, were sold to an American gentleman some years ago. I learn, in the third place, that Signor Enrico Pardo (the Botticelli agent mentioned above) and his partner, Signor Sanguinetti, have been condemned to pay 140,000 lire each for having sold illegally to an unknown purchaser the bust of Bindo Altoviti, modelled by Benvenuto Cellini. The Pope's government was so jealous of the safe keeping of this masterpiece that it caused it to be chained to the wall of the reception-room of the Altoviti Palace in the Piazza di Ponte S. Angelo. The bust was removed to Florence in 1888, when the Altoviti Palace was demolished to allow for the widening of the bed of the Tiber." — *Exchange.*

Afridi Wax-cloth. — Mr. George Watt, the Reporter on Economic Products to the Government of India, has succeeded in inducing the Afridi wax-cloth workers to impart the secret of their craft, which has hitherto puzzled all inquirers into Indian industries. Afridi wax-cloth, a kind of raised colored painting on cotton fabrics, has been made almost from time immemorial, and is a well-known product of certain workshops in Peshawar, Lahore, Calcutta, and Bombay; but until Mr. Watt set about his inquiries complete ignorance prevailed, outside the circle of artisans, as to the constitution of the medium employed. With the assistance of Mr. Roe, the Secretary to the Peshawar Municipality, Mr. Watt was able to ascertain that the medium, known as *roghan*, is a peculiar product of the safflower seed. The method of preparation, which is carried on entirely at Peshawar, is to boil the oil — expressed from the seeds by cold pressure — for twelve hours, and then throw the heated fluid into shallow pans of cold water. Under this treatment it swells up into a thick jelly-like substance, which is the *roghan* of commerce. Before being applied to the cloth it is mixed with some mineral color and drawn out into fine threads on a pointed style, with which the pattern is traced. The operators, who are invariably Afridis, attain a very high degree of skill, and possess marked artistic abilities. The weight of Afridi wax-cloth — an Afridi woman's costume would turn the scale at over thirteen pounds — makes it unsuitable to articles of European dress; but the ever-increasing demand for household drapings gave a ready outlet for the Afridi artisan's skill, to which he has readily adapted himself. Careful tests made in Calcutta also showed that as a waterproofing material, or as a material to be used in the manufacture of linoleum, *roghan* has a distinct claim to careful consideration, and is in some respects superior to linseed. Systematically exploited, there would appear to be a promising future before this industry. — *The Times of India.*

The Commercial Value of the Paris Exposition to Foreigners. — The French Customs Department has just published a report for 1900, which throws much light on the direct commercial results of the recent International Exhibition at Paris. Fifty-nine countries forwarded their merchandise (food and drinks not included) to the value of 250,000,000 francs, but the sales amounted to only 7,500,000 francs. The United States sold to the value of 1,657,000 francs out of 29,000,000 francs; Germany, 1,510,000 francs out of 23,000,000 francs; England, 905,000 francs out of 20,000,000 francs; Italy, 389,000 francs out of 26,000,000 francs; Russia, 352,000 francs out of 22,000,000 francs; Belgium, 255,000 francs out of 19,000,000 francs; Austria, 188,000 francs out of 23,000,000 francs; and Hungary, 166,000 francs out of 42,000,000 francs. Customs duty to the amount of 778,000 francs had to be paid on these sales, nearly half of which consisted of machinery, artistic objects figuring for only 55,000 francs. Taking the general imports for the year 1900, the foreign merchandise at the Exhibition represented only 4.18 per cent, and the sales only .16 per cent. "The various amusements offered to the public," remarks the *Messager de Paris*, "may have been manifold, but the capital expended has been enormous, as had been predicted by all those who, remembering the exhibitions of 1867, 1878, and 1889, justly maintained that that of 1900 would not be successful. — *N. Y. Evening Post.*

An English Jeer at our Architecture. — The negotiations between an Anglo-American syndicate and the London County Council for the acquisition of a large block of land in the Strand for the erection of a "world's wonder," in the shape of a mammoth office-building, have been broken off for the present on a mere trifle, writes John Hollingshead. The syndicate demands a lease for 999 years, just a little short of eternity, and the London County Council find that they are only empowered to grant a lease of ninety-nine years — a slight reduction. Every devout Londoner will call down all the blessings of creation on the Local Government Act which imposes these fetters on municipal action. The design of this mammoth building, as far as the plans have been disclosed, is to be of the Early Packing-case order of architecture developed by the sucking Palladios of Chicago, and sometimes known as the Perpendicular Goth and Vandal style. We have a feeble imitation of this penal architecture at "Queen Anne's Mansions," within "measurable distance," to use tailor's English, of Westminster Abbey, but no one has yet proposed to face Sir William Chambers's façade of Somerset House — much esteemed by persons who respect "Shakespeare, taste, and the musical glasses" — with a building like a glorified cotton-mill in Lancashire, adorned with Twelfth-cake ornaments. Such buildings may or may not tempt and encourage earthquakes, but they will certainly eclipse all our candle-lamp "monuments." — *Pall-Mall Gazette.*

The Number of the Architects to be eligible for New York Municipal Work. 80

NOTES AND CLIPPINGS. 80

THE Continental Insurance Company, of New York, has published an interesting account of the fire at Paterson, with photographic illustrations, showing very effectively the value of reasonably fireproof construction in checking a conflagration, and the danger of the mixture of wooden and brick buildings which prevails in all our large cities except New York. Briefly, the Paterson fire began in a wooden shed, spread, aided by a wind blowing at the rate of sixty miles an hour, to a block of ten wooden houses near by; then, its intensity having been augmented by the additional fuel, it seized on a cluster of buildings, consisting of a large brick stable, surrounded by wooden sheds. The flames then burst through the rear windows of a block of brick stores close by; while the showers of sparks set fire to other wooden buildings in the neighborhood; and the conflagration, fed by the combination of brick buildings filled with wooden floors and inflammable goods, and structures entirely of wood, soon swept everything before it, until it was stopped at five points by brick buildings, from one to five stories high, but having in most cases blank walls on the side most exposed to the flames. The interior woodwork of some of these brick buildings was burned, by fire getting in through unprotected windows; but it appears, more evidently, perhaps, than ever before, that a good blank wall of brick, even if twelve inches thick, or less, is impenetrable to almost any conflagration.

ANOTHER lesson that the Paterson fire, like several other recent ones, teaches is that a really fireproof building forms a bulwark against the spread of a conflagration which is of incalculable value. How many millions of dollars were saved to the insurance companies of Paterson by four or five brick walls it would be difficult to say, but the amount was certainly large enough to make it worth while for underwriters to encourage the building of plain brick walls and terra-cotta floors by the utmost possible reduction in premium rates. We do not say that a hotel of iron and brick or concrete, but with large, unprotected windows, ought to be insured at a rate which would not cover the probable loss in case a fire occurred near it; but where the owners are willing to add to their solid brick walls and floors of masonry wire-glass windows, or tin-covered shutters, they should be encouraged by a reduction of their premium rates to the lowest possible point, the insurance-companies bearing in mind that in case of a large fire in the neighborhood, such a building would probably save them, by keeping the fire back, more money than the premiums on it would amount to in a hundred years. In the same way, every dwelling-house owner in a city who builds with iron floor-beams, joining two solid party-walls, is, virtually, erecting a fort against conflagrations, and should be encouraged in the same way.

THE insurance-companies are said to have used the Paterson fire as a pretext for a twenty-five per-cent increase in premium rates everywhere, on everything except mercantile buildings and merchandise. Practically, the fire seems to have demonstrated, even more strongly than before, that a mercantile building is the worst of all risks, while modest brick dwellings, with solid party-walls between them, possess unexpected powers of resistance, so that the logic of increasing the rates on the latter, and leaving them unchanged on the former, will not be quite clear to architects; but, as they have learned that any questions or suggestions on their part seem only to call down on them a storm of abuse from the underwriters, they are likely to keep their observations to themselves. Meanwhile, however, speaking in behalf of ordinary people, it may be well to call attention to the disasters which Boston, particularly, is preparing for itself by its neglect to extend the fire-limits to the outlying wards. As Paterson has just shown, as Boston itself showed thirty years ago, and as it will show again before many months, a mixture of wooden and brick buildings is a continual invitation to a terrible conflagration; yet Roxbury, Dorchester and Brighton are filled with wooden structures, in many cases tenement-houses, four or five stories high, among which a fire, if it should once gain headway, might spread for miles. It is true that many owners, appalled at the danger, now build of brick, although not required to do so; but the number of brick buildings is too small to offer any effective barrier to the spread of a conflagration; and, as no law can, in this country, compel a man to pull down a building erected in conformity with the regulations then in force, there can be no radical change until the wooden buildings have been burned away, — and paid for twice over, it may be remarked, by the holders of insurance policies. It is, therefore, those who hold, and pay for, contracts of insurance who must, ultimately, buy, at an enormous cost, these wooden buildings, before the ground can be made ready for better ones. It is common to imagine that the underwriters exert their influence in favor of greater security of construction, and that, if the wooden suburbs of Boston were really so dangerous, they would second, before the Legislature, the urgent appeals of the Commissioner of Buildings for the extension of the fire-limits; but the underwriters trouble themselves very little about dwelling-house property, which, even in such localities, pays a disproportionately high premium rate, devoting their lamentations, and their objurgations against architects almost entirely to mercantile risks, which are notoriously insured too low, owing to the competition of the companies for large policies. We should be as much pleased as anybody to see the suggestions of the underwriters in regard to the construction of mercantile buildings generally complied with, and have always done our best to show the value of them; but architects look impartially on all classes of buildings, and the assistance of the underwriters in rating dwelling-house property fairly, and in promoting legislation to protect it, would be appreciated by them.

IN the death of Mr. Henry G. Marquand American art loses one of the sincerest and most faithful friends that it has ever had. For nearly fifty years he has been perhaps the most conspicuous and most intelligent of all American patrons of art, as well as the most generous and unwearied in all endeavors to educate the public taste, and bring to the minds of the people the happiness and refinement which art can bestow. Although of a fortune modest in comparison with the gigantic wealth of some of the beneficiaries of the system of high protection, Mr. Marquand, early in life, was able to surround himself with the beautiful things which he loved and understood so well, and he made it a matter of conscience to lead the way in the path of artistic cultivation. His house was one of the most refined works of the late Richard M. Hunt, and was filled with the best attainable decoration and furniture. Two of the ceilings were painted on canvas for the house by Sir Frederic Leighton, and higher praise could hardly be given them than to say that they were worthy both of the artist and of his patron. It was not, however, for himself that Mr. Marquand collected beautiful objects. He had been among

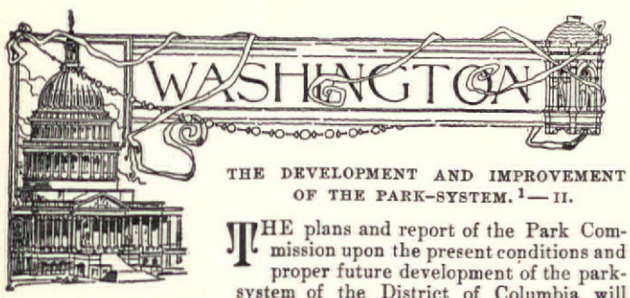
Entered at the Post-Office at Boston as second-class matter

the first, as he was the most energetic, in endeavoring to raise funds for the establishment of a Museum of Fine-Arts in New York. As our readers know, the Metropolitan Museum was, in the beginning, entirely a private enterprise. The city gave a site for the building in the Central Park, but the building was erected, equipped, maintained and filled with works of art wholly by private generosity, and among the public-spirited men who gave their time and money to the undertaking Mr. Marquand was the chief. Not only did he, with the others whose memory is so affectionately cherished in New York, contribute money enough to build a structure adequate for what they foresaw would be required of it, but he is said to have given to the Museum, during his lifetime, works of art to the value of more than a million and a half of dollars. It is a pleasure to think that Mr. Marquand, and many of his associates, lived long enough to reap the reward of their good deeds in the knowledge that the Metropolitan Museum has been one of the most important factors in the refinement and elevation of the people of New York; and, although it has now far outgrown its early limits, and has, by bequests and gifts, become, perhaps, the most richly endowed institution of the kind in the world, it was the energy and unselfishness of these good men which made it possible; and, without Mr. Marquand, Mr. Johnston and their friends, New York would, very probably, be still without any fine-art collection open to the public.

MIDDLE-AGED people will hear with regret of the death of Albert Bierstadt, for many years the most noted of American landscape-painters. It must be nearly half a century since Mr. Bierstadt startled and delighted the unsophisticated American public with a series of very large paintings of imposing pieces of natural scenery in the Rocky Mountains and elsewhere. These pictures were executed with great talent, if not with very profound feeling, and the painter would probably, in these days of more extended knowledge and sounder criticism, have been developed into an artist of the very highest rank; but, in an evil moment, the showman got hold of him, and it was found profitable to carry his large canvases around the country, fit them up with a frame of curtains, illuminate them by artificial light, and exhibit them to awestruck audiences at twenty-five cents a head. To paint with the object of astonishing uncultivated people, with the aid of glaring lights and theatrical accessories, would spoil the greatest artist that ever lived, and, even if it did not spoil the artist, it would ruin his reputation among people of discrimination, so that it is not surprising that Bierstadt's less pretentious works, some of which were of great merit, were overlooked, and that a suspicion of charlatanism fell upon him, which was not lessened, in the minds of those who knew the scenes which he painted, by the boldness with which he improved upon nature for the sake of pleasing his audiences. This manner of viewing fine-art was, in that day, at least pecuniarily profitable; and before advancing public taste had fully decided to disapprove of the theatrical display of pictures, he was able to console himself with a considerable fortune for the loss of his preëminence among American painters, and for many years, he had lived quietly, painting little, or, at least, exhibiting little, but enjoying the friendship and regard which his many kind deeds brought him. Some time, we trust that it may be possible to get together some of Bierstadt's less pretentious, but better studied, pictures, and show them, with some of those of Moran and Church, who painted similar subjects at about the same period. The comparison between these three, in the light of our present views of landscape-painting, would be extremely interesting; and, in fact, we can hardly think of anything more interesting, as a "between season" affair, than a retrospective exhibition of American landscape-painting, taking in Bierstadt, Church, McEntee, Thomas Moran, Kensett, William Bradford, Hunt, Gifford and Inness, with, perhaps, a few others. We may be sure that Americans would have no reason to be ashamed of their painters of the last generation, and, if La Farge and Richards would consent to be represented in the collection, it would not be easy, in any country in the world, to get together a greater variety of beautiful work of the kind.

THE New York *Times* makes a suggestion which is of great importance in connection with the energetic movement now in progress for securing the abolition of the customs duty on works of art. This duty, we need hardly say, has, apparently, not a single defender. Nearly all the respectable artists in the country have united, at short intervals, in vigorous protests against the barbarian policy of depriving the country of the costly, but precious, means of instruction in refinement and taste which so many of our citizens would bring here if we would let them; Congressmen, who have the remedy in their hands, individually disclaim all sympathy with the exclusion of such treasures; yet, collectively, they are unwilling to do anything to modify or repeal the existing law. Meanwhile, the most precious pictures and statues in the world are rapidly disappearing from the market. Anything of the kind that reaches a public museum in Europe is, of course, thenceforth unattainable, and, as it happens, political and financial troubles have, just now, brought to sale an unusually large number of works belonging to private owners. The same troubles have affected the museums, so that they have, in many cases, less than their usual resources for making new acquisitions, and the moment is, therefore, particularly favorable for rich Americans to secure what will probably never again be within their reach. It is needless to say that the works of art which rich Americans buy are almost always exhibited with the greatest liberality for the public benefit, and it is the whole American people which is interested now in giving all possible opportunity to those of their fellow-citizens who are able and willing to do so to buy pictures and statues which are sure to be used for the general good. A year from now conditions may be changed, and, in any case, the best of the works now in the market will have been secured by the European museums; so that prompt action by Congress in doing that which Congressmen themselves almost unanimously acknowledge to be desirable, and which the people of the country have for years demanded, may be of incalculable value.

ARCHITECTS who read French, and, particularly, those who have been members of the Paris School of Fine-Arts, or of a school *atelier*, should not fail to get the issue for February 1 of *Le Monde Moderne*, which contains a charming article, by Paul Gsell, on the Prize of Rome students at the Villa Medici, with many illustrations, beginning with a brief, but very interesting, history of the foundation and early days of the French Academy at Rome. The origin of the institution is said to be found in the desire of King Louis XIV to possess in his palaces copies of the masterpieces of antique sculpture. Nicolas Poussin, who then resided at Rome, was requested to take charge of the organization of the new school, but declined, on account of failing health, and it was not until 1666, a year after Poussin's death, that the new Academy was established, under the direction of the painter Errard. The regulations prescribed that twelve students should be admitted, six painters, four sculptors and two architects, all of whom must be French by birth, and Catholics in religion. They were forbidden to blaspheme, and were required to say their prayers morning and evening. In summer they were obliged to rise at five, in winter at six, and ten o'clock was bedtime all the year round. During their meals, one student, designated by the director, read history to them. The ambassador of France at Rome was requested to make occasional visits to the Academy, with his wife, as a polite attention to the students, and the sculptor Bernini, who understood the art of making friends, delighted the King and his Minister, Colbert, by volunteering to advise the young French artists. Great numbers of copies of pictures and casts of sculpture were made by the students and sent to Paris, with regular reports of the conduct of each member of the school. In 1792, the Academy was suppressed by the Convention, but it was reëstablished by the Directory, three years later, and the number of students increased to twenty-four. In 1803, the Academy, after having been lodged in various palaces in the city, was removed to the Villa Medici, where it has been domiciled ever since. For many years the French Academy has been very popular in Rome, both in the royal and papal courts. It will be remembered that, a year or two ago, an excellent portrait was published of the present Pope. This portrait was a reproduction of one painted by a student of the school, M. Chartran, to whom the Pope accorded the unusual favor of several sittings; and, from the other side of the Tiber, the Queen of Italy regularly visits the annual exhibition of works by students of the Academy, which is held from the first to the fifteenth of April. Among themselves, the students have various customs, and are subjected to various rules, for which we must refer our readers to M. Gsell's paper, where they will find also an interesting discussion of the merits of the present system of admission.



THE DEVELOPMENT AND IMPROVEMENT OF THE PARK-SYSTEM.[1] — II.

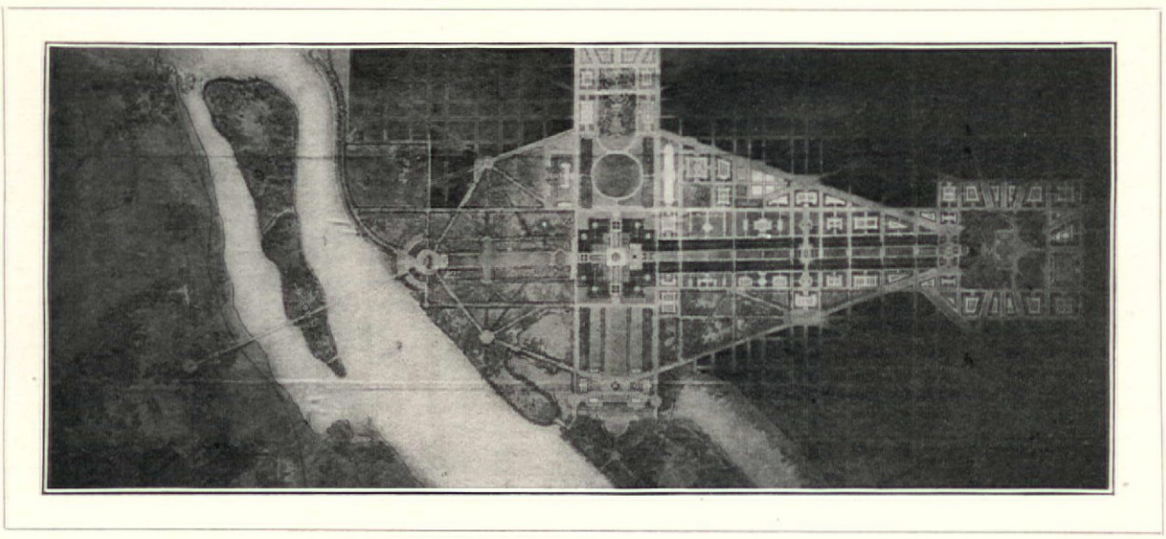
THE plans and report of the Park Commission upon the present conditions and proper future development of the park-system of the District of Columbia will come in the minds of those who are interested in national æsthetics to mark a stage in our intellectual progress, and, at the risk of giving a somewhat Hibernian turn to the metaphor, it might be added that the progress is not so much an advance as it is a return to the better sense and better taste of the founders. We have retreated to our base of supplies, and now we mean to march forward on the right road, with Washington and his lieutenant, L'Enfant, riding at the head of the column.

From another point-of-view, the material one, the conception of so splendid and costly a scheme by men of practical judgment and experience is highly significant of the greatness of our national prosperity, for their scheme involves the expenditure of as yet unreckoned millions of money. It may be that the plain people of the country will at first consider it as a dream impossible of realization.

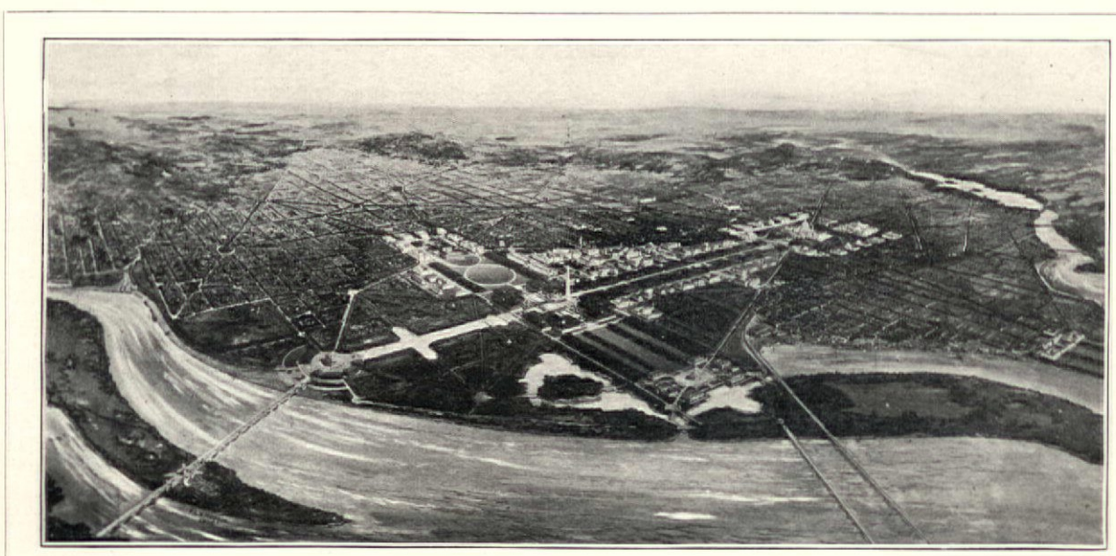
It is in fact, I believe, the biggest scheme of city treatment as yet projected, the most extensive problem in landscape-architecture which has been undertaken. So I am told, and we rather like to measure our achievements against those of all time and of the world, and to express them in superlatives.

Studied, however, in the light of a plan not only for present needs but for the Nation's life, it will come to be understood as no more than adequate, no less than a fitting expression of the Republic's dignity. The scheme will be laid before the people again and again in the technical journals, explained to them in word and picture in the important magazines and exhibited in some of the great centres until its lesson is learned. The lesson is one in the principles of an art which includes most of the arts, but which, as an essentially busy and utilitarian people, we have not as yet had time to study as it deserves. There is little doubt of the ultimate acceptance of the plan as the right one for Washington's development and adornment and as one perfectly practicable. The people will want this thing done for the country's sake, for their own education and edification and for their children and children's children. Whether they will soon be able to impress upon their representatives in Congress the assurance of their supporting the necessary appropriations is another matter.

There is much encouragement for us in the way this plan has come about. The awakening of our people to the beauty of a studied disposition of buildings in ordered landscape began with the Chicago Exposition of '93. Since that event the general interest in such matters has grown rapidly, as things well started have a way of doing in this favored land.



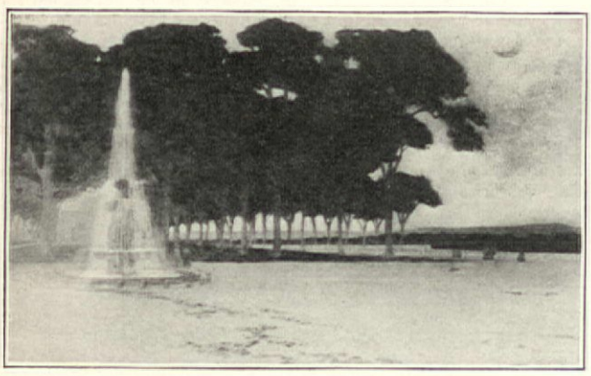
While the immediate impulse in this case came from the architectural bodies and art societies, it is true that persons of intelligence and taste have been working individually toward the same end for a long time. The Senate Committee on the District of Columbia happens just now to contain a good deal of this sort of intelligence and to enjoy in its present chairman the leadership of a man of more than ordinarily comprehensive attainments. Having acted with rare promptness upon the advice of the artistic professions, even to the extent of appointing the commission of experts nominated by them, the Senate, in presenting to the country the admirable result of their labors, looks to have it appreciated, accepted, and always strongly supported by those bodies.



The plan is admirable. It stands close criticism. We wanted a working-plan for the improvement of the national capital. Here is one which has grown out of close and comprehensive study of all the conditions. The Park Commission was given a free hand as to cost

[1] Continued from No. 1362, page 36.

of investigation. It was generously aided by the various departments and officers of Government. It covered the ground at home and abroad as no individual could hope to cover it. The membership of the Commission could not have been improved upon. We must now accept the plan it gives us as the best one possible, and work for its adoption. Let the promptings of individual talent — there are, alas, already those who would demonstrate how much better they



View from Base of Monument towards Arlington.

could have done it — be sternly disregarded, and let us work loyally together for the common good.

This should be all the more easy from the modest attitude of the Park Commission, which presents its beautiful project as simply an amplification of the design Pierre Charles L'Enfant worked out under the direction and assistance of Washington and Jefferson.

Major L'Enfant was a young French engineer of ability, who came highly recommended to Washington for the performance of this work. The work was admirably well done — and, incidentally, not entirely paid for, which is a way we have in republics sometimes.

This plan after a century's trial has had universal approval. It has been a model for city-building and improvement all over the world. It deals with Washington as distinctively a capital city. It provides a convenient and beautiful arrangement of streets in which the first consideration was the location of public buildings and grounds, the determination of each site in reference to every other site, and of lines of communication between them. It studies the reciprocal relations of buildings, vistas and axes, parks and pleasure-grounds, fountains and canals, monuments and museums, noble groupings of foliage and water decoration.

The present Park Commission found this plan, marred as it has been by deplorable but not incurable departures, perfectly adequate, with some elaboration, for all our needs of to-day and of the future, and they determined to adhere to it. They thereby "acquire merit."

Taking L'Enfant's Mall and his axial treatment of the Capitol, the Washington Memorial, and the President's house as their working basis or point of departure, they form in a study of the evident prototype of L'Enfant's design — Le Nôtre's masterpiece, Versailles — the inspiration of the project they so superbly demonstrate in this exposition at the Corcoran Gallery of Art. A summer tour to Rome, Venice, Vienna, Buda-Pesth, Frankfort, Berlin, Paris and London gave them a review of famous examples of city-making and landscape-architecture, and in their scheme for the beautification of Washington, they give us the charm of many noted places.

Here we shall rival the classic monuments and noble fountains of Rome, the broad-stretching vistas of Paris, the quays and embankments, bridges and general river-treatment of London, Buda-Pesth, Paris, and especially the grandiose conceptions of Le Nôtre, the unquestioned master of landscape art. Even a slight comparison of the plans of Le Nôtre's Versailles, of L'Enfant's Washington, and of the Park Commission's greater Washington, will disclose insistent analogies and resemblances which put the sources of inspiration beyond a doubt.

In Le Nôtre's plan the principle of axial relation followed to its ultimate conclusions gave the Latin-cross form, which is that of our own scheme. At Versailles are also those diagonal extensions at the sides and about the head of the cross which lends to Washington its peculiar kite-shape. The rond-point at the head of the cross, the radial system of roads and paths are again resemblances. In fact, the rectangular divisions of the garden-terrace at Versailles, if overlain with the secondary system of rond-points and radial avenues which run through the domain, would give the essential feature of L'Enfant's plan of Washington.

At the risk of repeating points referred to in a former letter, I wish to again call attention to certain strong features of the Commission's report:

The Commission has formulated certain precepts as to the locations of public buildings: (1) That only public buildings should face the grounds of the Capitol; (2) that new Department buildings may well be located so as to face Lafayette Square; (3) that buildings of a semi-public character may be located south of the present Corcoran Art Gallery, fronting on the White Lot and extending to the park limits; (4) that the northern side of the Mall may properly be used by museums and other buildings containing collections in which the public generally is interested, but not by Department buildings; (5) that the space between Pennsylvania Avenue and the Mall should be occupied by the District Building, the Hall of Records, a modern market, an armory for the District militia and structures of like character.

In all of these cases except the fourth cited it would be necessary for the Government to acquire by condemnation and purchase large bodies of ground, of high value about Lafayette Square, of lesser but still considerable value along Pennsylvania Avenue, and at moderate cost elsewhere.

The very generous and public-spirited action of the Pennsylvania Railway, through its President, Mr. Cassatt, in agreeing, should Congress decide to carry out the project of the Commission, to give up its grant upon the Mall, to remove its tracks and station thence to a site chosen for them, and to bear its share in the construction of a magnificent union station, in white marble and of Classic architecture, to tunnel Capitol Hill for its southern connection, and to eliminate grade-crossings as the engineers have planned, remove all obstacle to the beautification of Washington except the need of legislation and appropriations. To preserve uniformity of effect the Commission prescribes that all buildings public or semi-public in character to be erected within the limits of the general treatment proposed shall be designed in the Classic orders and built of white marble.

There is no space in this paper for a discussion of the Commission's proposals for park extensions and connections, for driveways and roads and bridges, quays and embankments. This part of their subject has been exhaustively treated and is of immense importance. Their plan involves the reclamation of the whole river-front of the city, which is to be made sanitary and sightly. Its present state is deplorable. The valley of Rock Creek from its mouth to the Zoölogical Park will be rescued from its present squalor and unloveliness. The river-roads will be improved and the beauties of the gorge of the Potomac above Georgetown brought into the scheme of parked driveways which are to connect the outlying parks and completely encircle the city. The fever-breeding flats of the Anacostia will become a water-park and the navigable stretch of that stream down to its junction with the Potomac will be restricted to a dredged and walled channel, out to which the bed will be filled on both sides.

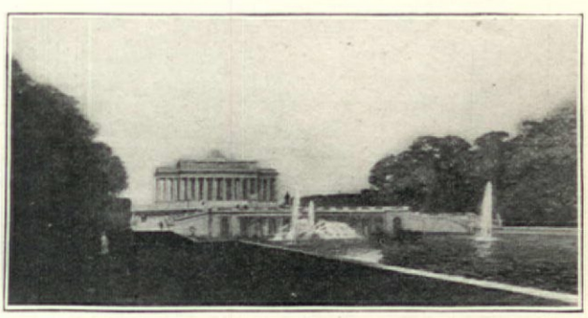
Another glance at the treatment proposed within the city proper and this attempt to sketch-in the mere outlines of the project will be done.

L'Enfant explained that the essence of his plan of the city was the idea "to preserve through the whole a reciprocity of sight." His radial avenues attain that end most admirably. These make, with the triangles and circles which occur upon the maps where they cross one another or cut the grillage of lettered and numbered streets, the glory of the city and give suggestions of infinite possibilities of enhanced beauty. This "reciprocity" is nowhere disturbed in the new plans.

Its application to the axes of the Capitol, the Washington Monument and Lincoln Memorial, the White House and the river arm of the cross is the basis of the whole development. The aberration of the actual site of the Washington Monument from the axial lines is cleverly adjusted. "The Commission proposes by a simple device of planting," says the Report, "to bring the Monument into the Capitol vista, so that the observer standing on the west terrace of the Capitol shall look off over a green carpet, bordered on each side by four rows of elms, to the Monument rising from a plain."

Beyond this border of stately trees will stand, on either hand, buildings in white marble of Classic design, uniform in scale and in ample grounds. Those on the north will house the museums and public collections; those on the south, the scientific bureaus. There will be space for this arrangement within the sixteen-hundred-foot width of the Mall.

The broadening of the base of the cross about the Capitol by taking in the squares giving upon the grounds to afford sites for buildings auxiliary to the Houses of Congress gives admirable balance to



Showing proposed Development of Site for Lincoln Memorial.

the plan and is delightfully convincing as seen in the views and model. The restoration of the beautiful Bulfinch gates, the fountains, terraces, basins, equestrian statues and approaches where the Mall ends at the foot of the Capitoline Hill will add great dignity to the view from the Mall. Incidentally, it is to be hoped, perhaps, that our new statuary may not be so inevitably horsed.

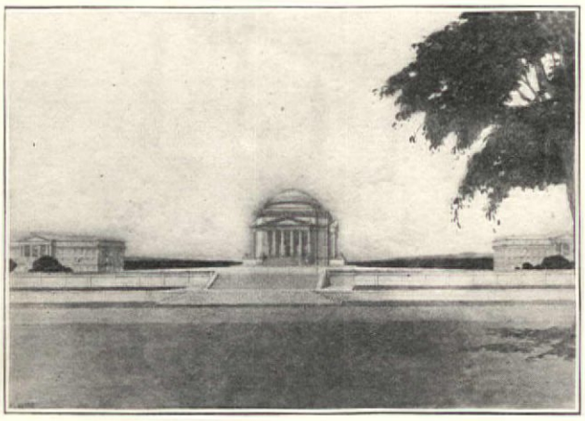
The terraces, with formal tree-masses and pavilions, broad approaches and a sunken garden on the west about the Monument will

add a proper base and ennoble the effect of the Monument without detracting in the least from its soaring height. In the whole plan of the Commission appears nothing more commendable than the setting given the great obelisk. A square measuring sixteen hundred feet on a side, described by the intersecting axes of the Capitol and the White House, at the full width of the Mall reservation, is terraced with marble walls and parapets. This encloses an interior square of twelve hundred feet, a sunken garden adorned with a water-decoration of cascades and a great round basin which marks the centre of the cross and in which the shaft of the Monument reflects. This formal garden, in the words of the Report, becomes "the gem of the whole park-system."

The Monument itself as a simple and noble expression of beauty and grandeur combined is, beyond measure of words, impressive. A mighty shaft of white against the blue, a pillar of purity against the clouds, with storm about its head or rising calm and glittering in the moonlight, it towers above the city and dominates the prospect from every point, as the great man whom it commemorates and typifies stands over the nation ever and guides the destinies he set in motion. It was fitting that his Memorial should stand at the heart of his city's beauty. There is a symbolism in its place upon this plan as the goal of every view.

Here again L'Enfant's idea lives. One may fairly well realize the effect of this terrace and garden by recalling the gardens of the Luxembourg, which, however, lack the superb vistas we shall enjoy here.

The grandest looks west from the Monument to the head of the cross-plan, over the garden down the long perspective of a great basin, again cruciform, between ranks of trees, to the rond-point. This circle is ringed with trees forming a peristyle from which radiate avenues. An eminence circumscribed by the encircling roadway will be crowned with the proposed Memorial to Lincoln, a Doric portico in rectangular form, 250 feet in length and 220 feet in width, on a continuous stylobate or base, approached by broad flights of steps on the east and west, and bearing a panel with appropriate



Suggestions for Public Buildings.

inscription. This portico will have groups of sculpture and be "surmounted by a central crowning group of statuary."

The avenues radiating from this centre lead to Potomac Park, to the Memorial Bridge, to Arlington, and by the Riverside Drive to the Rock Creek parks.

The whole parallelogram west of the Monument Garden has the width of the Mall, 1,600 feet, and extends for a mile to the Potomac. The canal, or water-avenue, which lies in the Capitol and Monument axis is 3,600 feet long by 200 feet in width. The treatment of the whole area about the top of the cross-plan is more sylvan and affords relief from the formalism properly held elsewhere. In the middle-distance curves the river, and beyond are the tree-covered Arlington hills against the sky.

The grouping of new Department buildings about Lafayette Square, the provision for Executive Offices and reception-halls in one of these, thus permitting the White House to remain exteriorly as it is, the creation of a beautiful vista southward from it over the White Lot, the Monument Gardens, Washington Common, with its proposed stadium, playgrounds and theatre, to the Memorial to the Republic by the river-shore, where will also be made public baths, and lakes for swimming, boating and skating — all these are admirable features among others for more extended reference than there is space for now.

The proposed acquisition of the space between Pennsylvania Avenue and B Street, now covered with buildings of a most unsightly sort and forming a district of sordid, unsanitary and immoral conditions, a region of slums, and the use of this ground as sites for a municipal building, for enlarged modern markets, for an armory, a hall of records or deposit for the Governmental archives, and for like purposes, has been long urged, and will commend itself to every traveller who may have been shocked at the present condition of this, the city's most important, avenue.

It should be noted by those who may regret the loss of Downing's Mall that in the masses of forest and park treatment appearing in the Commission's plan, upon the acquisitions south of the Mall and in the parts toward the Lincoln Memorial, there will be given back an equal or greater area less regularly planted and showing within its formal boundaries something of the picturesque, or English, style which we have been accustomed to associate with the idea of a park. And this sentiment is a thing to be reckoned with as something which comes to us through an inheritance of many generations. It was in Pope's time that an overdoing of the Italian garden and absurd exaggeration of the topiary art began to be ridiculed out of the way of the new natural school, which has since so generally held sway. The formality of this essentially academic and formal work of the Commission may not at once commend itself to people who have grown up in another tradition. This stiff-set piece of landscape-art, showing in every feature the law and order of Classic art, may cause lovers of the Romantic School a certain weariness of spirit.

The first sight of Versailles, for instance, the long straight avenues, geometric figures at every crossing of the ways, the trees in ranks, the hedges clipped to forms of stone, the vast perspective between mathematical parallels of foliage, the rococo distortion and imprisonment of nature's free grace, may bring a lonesome feeling, a yearning for the sight of the vagabond cow-path in the big woods. Mother Nature seems remote. Her sweet, intimate beauty is not here. Instead reigns a pagan god. A bust of Pan leers from the *quincunx*. Well, Nature still sits upon her proper throne, but here Art reigns of right. And so in these plans of the Commission we must let these capable artists teach us what is best. And as we study their scheme, as a whole and in detail, we must grow more and more deeply impressed with the splendidly comprehensive grasp and knowledge and refinement of taste which have gone into its invention. Their presentation of it in their report and in this exhibition of plans, sections, models, views, and bits of detail in beautiful rendering, with hundreds of enlarged photographs of examples of landscape-architecture from foreign places is, beyond words, convincing and beautiful. One hopes that means will be found to let it be seen in other centres of population, that its incalculable educational value may be felt far and wide among us. Already something toward this end has been arranged, and the exhibition goes to Chicago for a time after March 1st, and will later be seen in New York.

Finally, it is comforting to know that, so far, all projects for new public buildings coming before Congress in this session are within the lines of the Commission's plan:

A building for the use of Congress is to balance the Library at the northeast corner of the Capitol grounds. Another square in that place will be given to a building for the Supreme Court. The new Department Building of State and Justice will occupy the square bounded by Seventeenth Street, Pennsylvania Avenue, Lafayette Square and H Street. Negotiations are in progress to purchase the square on south side of Pennsylvania Avenue east of Fourteenth Street, for a Hall of Records.

It is proposed at once to remove the trees from the Capitol and Monument axis.

Thus are the essential features of the Commission's plan already being ratified by Congressional approval.

COMMON ACCIDENTS IN BUILDING.

THE following memorandum on the causes of common accidents that occur on buildings in course of construction or repair, and hints for their prevention, has been issued by the [English] Home Secretary.

In the memorandum an attempt is made to explain and illustrate those accidents the cause of which may be considered controllable by the builders and workmen. The dangerous conditions in building-operations may be divided into two classes — (*a*) Those arising from imperfect scaffolding, and (*b*) Those arising from the lifting and carrying of material.

SCAFFOLDING.

1. The two principal methods are known respectively as the North and South Country systems. The Northern, as the name indicates, is principally used in Scotland and the North of England, although of late years it has also found favor in the South; the other method (see Fig. 1) is essentially the South-country system.

2. The first method is invariably used in conjunction with power, generally a steam crane. When one crane only is necessary it is fixed upon a triangular platform built upon three legs, one at each angle, and is raised to such a height as to be well over the building to be erected. The crane stands over the principal, or king, leg. Owing to the guys it cannot make a complete revolution; if power is required that can be utilized on all parts of the building, the erection has a square platform with a leg at each angle, two cranes are then fixed, being placed diametrically opposite to each other.

3. The three or four legs, as the case may be, are of framed timber, bolted, and are weighted to the ground by masses of brickwork. The whole is so well built that accidents occurring through faults of construction are extremely rare.

4. The greatest dangers arise when the crane is imperfectly fixed, and when the weight of the crane engine and load is too much for the king-leg on which it rests, and when the legs are not sufficiently far from the king.

5. With regard to the first point, the guys of the crane should always be carried to the centre of the secondary legs, and chained down to the masses of brickwork which weight these legs at their feet. This chain requires frequent examination, especially when a

heavy load is being raised, as, owing to the vibration of the scaffold, it becomes loose, and, if not tightened, the crane would lose its rigidity, and accidents would be likely to occur.

6. In the second case where the weight is great, the king leg should have an additional centre upright running from top to bottom. (See Fig. 2, which is a plan of a king leg.)

7. The second form of scaffolding presents many points of interest. In order to render this report more intelligible, notes are given on the sketch (Fig. 1) which explain the technical terms used. There are two varieties again of this scaffold, and their use depends upon the material of which the building is being constructed — viz., either of brick or stone.

8. Where bricks are in use, one row of standards and ledgers only are necessary, the putlogs resting outwardly on the ledgers and inwardly on the wall (where header-bricks have been left out for their reception).

9. On stone buildings, and more especially when ashlar fronted and where an opening in the wall would leave a permanent disfigurement, a double set of standards, etc., are necessary to carry the putlogs. (See Fig. 3, which is a section of what is known as a mason's scaffold.)

10. A few points with regard to these erections.

11. The different marryings, tyings, etc., should be carefully watched, as scaffolds have been known to come down owing to the cords slipping. This happens more especially when cords have been used damp, the influence of a hot sun causing them to relax considerably. Wedge-driving between cords and posts is the usual method of tightening.

12. The boards on which the men work should be carefully kept in position. Figure 4 shows the usual position of the boards. Carelessness may, and does, result in these losing their place, and if by so doing they take the position shown on Figure 5, what is known as a trap is formed. Figure 6 illustrates the working of a trap. It will be noticed that when on the boards it is not easy to tell where the putlogs are. This creates to a large extent the danger. A certain preventive would be for the putlogs to be used in pairs; the boards then, instead of overlapping, could be placed end to end (see Fig. 7); in overlapping, boards get out of place, and a second man of two may catch his toe against the end raised.

13. Two of the commonest forms of accidents occur on these scaffolds, the falling of workmen and the dropping of the material from the upper floors of the erection. On the outside of the scaffold, also at the ends, a guard-rail should be lashed to the standards about 3 feet 6 inches above the scaffold-boards. This would obviate the first danger. With regard to the second, the danger from falling material is much to be deplored, as, though it can occur in many ways, it is, as a rule, the result of great carelessness. A board on edge running along the outside of the scaffold, but within the uprights and nailed to them, and again at the ends, would, to a great extent, prevent this class of accidents. Unfortunately, this board cannot be fixed on the inward side of the scaffold, as it would interfere with the free use of the workmen's tools. Figures 1 and 3 show the guard-rail and board on edge.

14. A mason's scaffold should be supported in such a manner that no opportunity could occur for it to fall away from the building. Figure 3 shows the shoring which is the usual method of preventing this where room permits — but this cannot be applied in a street, and in that case the scaffold should be tied to the inside of the buildings by poles through the openings.

15. There are other conditions of risk involved in insufficient width of runs, and in the use of centring improperly supported. A run is commonly seen only one board wide (9 inches). It is needless to say that this width is dangerous; 18 inches is the least that should be allowed. A run for continued use would be better made of two 3″ x 11″ planks if two planks are used. A slip of wood can be nailed across the undersides to keep them together. Figure 8 is a plan of a working-platform surrounding a courtyard or well, and gives three examples of runs which are commonly used, but which are not satisfactory.

16. Improperly supported centring is seen only in cheap work. Figures 9 and 10 give an example of what is meant. It will be noticed that the supports to the centring of Figure 9 are kept in their position entirely by the lateral pressure exerted by the stay *A*. It follows that if this pressure is eased sufficiently, say by shrinkage, it is more than probable that the centring and a large portion of the unfinished arch would fall. Figure 10 shows the centring properly supported. All supports to centring should rise from a solid foundation.

16*a*. Painters' boats occasionally fall owing to the use of defective cordage and supports. Care is the only remedy that can be suggested.

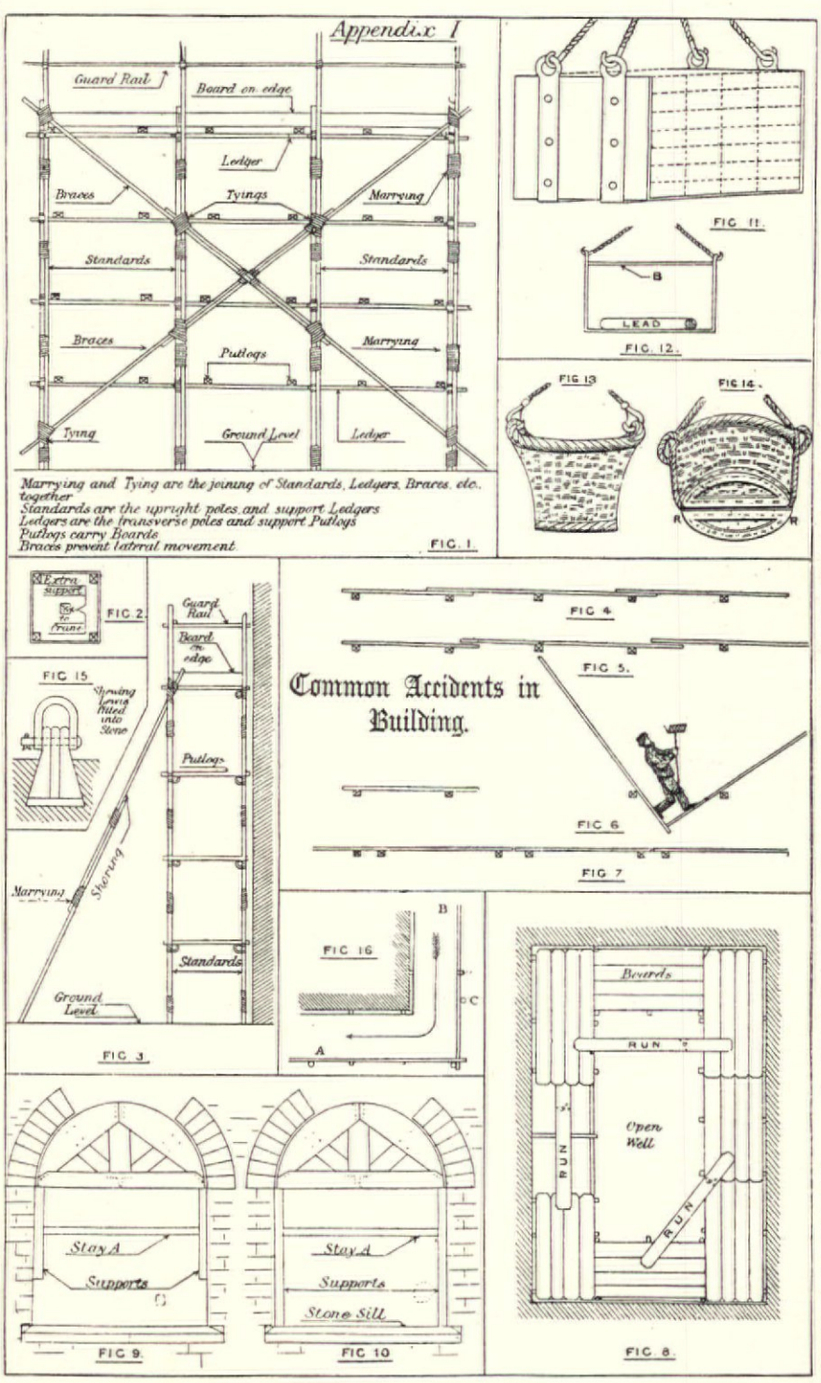
16*b*. Gantries, especially those erected over the public way, having to carry great weights, should be effectively strutted and braced, and timber of sufficient strength used.

THE LIFTING AND CARRYING OF MATERIAL.

17. Very little danger arises during the lifting and carrying of material so far as the power in use is concerned. The accidents generally occur owing to the defective manner by which the material is secured to the crane, pulley-wheels, or whatever the arrangement for lifting may be.

IRONWORK.

18. Ironwork is principally used in the form of girders or columns. They are sometimes slung by a chain round the middle and as evenly balanced as may be. There is considerable danger of this chain slipping, however well balanced (more especially if the load when swinging is tilted, say by receiving a jar through touching some part of the erection) and thus allowing the material to fall. To prevent this a second chain may be run from each end of the column or girder to a point some distance up the supporting chain; but the best remedy is a "softener" — *i. e.*, an old bag or sack put round the ironwork first, and the chain turned twice round it over the



"softener" and knocked as close as possible; then no slipping will take place.

The same applies to timber.

TIMBER.

19. Timber in lengths can be carried in the same manner as the iron girders, but owing to the greater friction set up between wood and iron, it is not so likely to slip as the former. The same precautions, however, are necessary.

BRICKS, SLATES, ETC.

20. Bricks, slates, etc., in large quantities are slung in crates, in smaller quantities in baskets, and in small work are carried in hods by laborers.

21. The crates (Fig. 11) will carry as many as 350 bricks. It will be noticed that they are not fitted with sides. This is to facilitate loading. The chief danger arises from their use when they are improperly packed. When suspended the pull on the handles causes the ends to take an inward slope. If the crate is tightly packed this pull creates a pressure on the material, and tends to keep it in position; but if loosely packed, the absence of sides would be a source of danger, as the material could easily fall out.

22. If a similar crate was used to carry a roll of lead, it would be necessary to place a stay (*B*, Fig. 12) across the top, to counteract and relieve the strain at the bottom.

23. When baskets are used, the danger lies in the handles. If they are hooked to chains, which is the usual method (Fig. 13), the weight may, and does, cause them to give way. One remedy is for the chain or rope to be carried round the basket, as shown in Figure 14. The pieces of wood marked *R*, if fixed as shown, would give the basket a level bottom, and would also tend to prevent the rope slipping. A better course would be so to construct the basket that the material of which the handles are made should be carried down the sides and along the bottom of the baskets, and well secured thereto. In any case care should be taken to see that the baskets are strong enough in the first instance, kept in proper repair, and not overloaded, and that spring hooks be used on the slings.

STONE.

24. There are several methods of lifting stone. It can be lifted in the same manner as ironwork, or may be suspended by means of a "lewis," or, again, by means of nippers.

25. The first method is perhaps the safest, but is generally used for undressed work only, as the chain is apt to break up any finished edges, etc.

26. The second method — by a lewis. A hole is cut into the stone wider at the bottom than at the top, three pieces of iron, as shown in Figure 15, are fitted into it, the outside, or splayed, pieces first, and the rectangular centre-piece last. A bolt running through the top of each fixes its position, and at the same time secures a ring into which the hook by which it is to be lifted is placed. This arrangement will lift a very great weight. They are made in all sizes to suit; the softer the stone the deeper they ought to be in proportion to the weight. The risk of its giving way if the stone is not free from vents, or when the lewis does not fit the hole, or, again, if the weight is not evenly distributed, is considerable. Its use with perfect safety can only be left to the judgment of the mason.

27. The nippers clutch the stone on the outside. Danger may arise if the small holes picked out to receive the nippers are so near the top edges of the stone that the points drag out; or again, the centre of gravity may be above the points, causing the stone to turn over and fall.

28. It is, of course, assumed that the plant in use has been, both in point of quantity and quality (and the first is of equal importance with the second), fully sufficient. It is regrettable that often in actual practice this has been found not to be so. Inferior tackle has been, and is, responsible for many accidents. Many lives, again, could have been saved if a little forethought had been used, and compliance made with those unwritten rules by which workmen should be guided. Figure 16 will give a clear illustration of what is meant. A laborer, in building a scaffold, required a ledger at point *A*. He fetched it from point *B*. He carried it upon his right shoulder, and in turning the corner in the direction of the arrow, the end of the pole struck against standard *C*. The recoil immediately knocked him off the scaffold. If the pole had been upon his left shoulder the blow would have fallen harmlessly, and his life would not have been lost.

The following suggestions, if carried out, would tend materially to reduce the number of accidents occurring on buildings in course of construction or repair: —

(1) All working-platforms above the height of 10 feet, taken from the adjacent ground-level, should, before employment takes place thereon, be provided throughout their entire length on the outside and at their ends —

(*a*) With a guard-rail fixed at a height of 3 feet 6 inches above the scaffold-boards. Openings may be left for workmen to land from the ladders, and for the landing of material.

(*b*) With boards fixed so that their bottom edges are resting on or abutting to the scaffold-boards. The boards so fixed should rise above the working-platform not less than 7 inches. Openings may be left for the landing of the workmen from the ladders.

(2) All "runs" or similar means of communication between different portions of a scaffold or building should be not less than 18 inches wide. If composed of two or more boards they should be fastened together in such a manner as to prevent unequal sagging.

(3) Scaffold-boards forming part of a working-platform should be supported at each end by a putlog, and should not project more than 6 inches beyond it unless lapped by another board, which should rest partly on or over the same putlog and partly upon putlogs other than those upon which the supported board rests.

In such cases where the scaffold-boards rest upon brackets, the foregoing suggestion should read as if the word "bracket" replaced the word "putlog."

N. B. — Experiments have shown that a board with not more than a 6-inch projection over a putlog can be considered safe from trapping or tilting.

(4) All supports to centring should be carried from a solid foundation.

(5) In places where the scaffolding has been sublet to a contractor, the employer should satisfy himself, before allowing work to proceed thereon, that the foregoing suggestions have been complied with, and that the material used in the construction of the scaffold is sound.

ARTISTS' PROTEST AGAINST THE TARIFF.

THERE are many reasons why the present time seems particularly opportune for a renewal of the movement for a repeal of the tariff on works of art. Probably there has never been so general an interest in the subject throughout the country as has been aroused by the recent purchase of great masterpieces of the world's art by several Americans of great wealth and liberality. While the Government of Italy has placed every legal obstacle in the way of the sale and exportation of the artistic treasures of its citizens, realizing that its works of art are one of the most valuable assets of the country, our own Government strives to render the importation of these same works of art difficult or impossible, and with such a measure of success that many great works actually owned by American citizens are retained abroad because the tax on their importation is too heavy to be willingly borne. At a time when the United States is the richest and one of the most powerful countries in the world, when a growing taste leads us increasingly to desire those things of beauty which our wealth enables us to command, and when financial embarrassment in many countries of the Old World is placing upon the market art treasures which a few years ago could not have been purchased at any price, why should our Government alone among those of civilized peoples treat art as a luxury, the indulgence in which must be penalized?

It can only be as a luxury that art is taxed, for with our overflowing treasury, necessitating the immediate reduction of taxation, the comparative small revenue arising from the tariff on works of art could readily be spared; while the repeated and continuous efforts of the artists of this country to secure the abolition of that tariff show better than could anything else the absurdity of considering that a protective tax which its supposed beneficiaries are most desirous of abolishing. Yet, it seems scarcely necessary to argue at this day against that view which considers as a mere "luxury" one of the greatest of civilizing forces and one of the most permanent forms of wealth, and to point out that no one consumes works of art, but that they remain in the country, ultimately devolving by gift, bequest or purchase to museums or other public institutions, where, as the property of the people, they diffuse education and culture forever.

In common with all other people of taste and refinement, the artists of the United States are opposed to this tax on civilization. Through an organization formed for that purpose they advocated its abolition for years, and secured, first, a reduction of one-half, and then its entire removal. In the Dingley tariff, however, the tax on works of art was reimposed, and in a worse form than ever, for the new tax made no exception of "antiquities," under which name the works of the old masters were formerly admitted free of duty. We believe that American artists ask and need no protection, and we would willingly see the total abolition of any tax whatever upon the importation of works of art. Certainly we not only need no protection against the works of the old masters, but we need those works, and heartily desire bringing into this country as many such as can be procured. We can see no possible interest that could be harmed, and many that could be helped, by the placing upon the free list of all works of art created fifty years before the date of importation, and we hope that at least so much freedom of importation may be granted.

As the National Free Art League was dissolved, after apparently accomplishing its purpose, the artists of the country can act only through their regular organizations. We therefore purpose to bring the matter of the tariff upon works of art once more before the various art-societies of New York, and ultimately before the Fine Arts Federation, in the hope that Congress will be induced to abolish or modify the present tax.

THE NUMBER OF THE ARCHITECTS TO BE ELIGIBLE FOR NEW YORK MUNICIPAL WORK.

NEW YORK, N. Y., February 25, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — In your editorial reference to the bill "to facilitate the selection of competent architects for municipal work in the city of New York," in your issue of February 22, one point of great importance has been overlooked. There is no intention to limit the "eligible list" to 100. This is merely a limit beyond which the Fine-Arts Federation are not compelled to furnish names to the Mayor.

It seemed necessary, as a matter of public policy, to give the Mayor power to keep the "eligible list" filled up to the limit of 100 even if the Federation for any reason should fail to act. Beyond that point it seemed desirable that the Mayor should not have this power unless the Federation did present him lists of names from which to appoint, for very great care would be necessary in the choice of architects after such a list of 100 had been named, and there might be years when the Federation would not feel inclined to furnish any names whatever. It is, however, intended to make the list just as large as possible, so that eventually it will include all the men of reputation in this country.

We have great hopes that this list will eventually become a roll of honor, and that, as all the younger members of the profession will desire to be placed on this list, it will furnish an additional incentive to them to avoid questionable practices and will thus tend on the whole to raise the *morale* of the profession at large.

Yours very truly, HENRY R. MARSHALL, *President*.

NOTES & CLIPPINGS

THE FOUNDRY CHURCH, WASHINGTON, D. C. — One of the oldest houses of worship in Washington, the Foundry Church, which more than one Methodist President has attended, is about to be torn down to make room for a modern office-building. The property has been bought by Thomas F. Walsh, the rich Colorado miner. As the story goes, he happened in at a fair which was given to raise money for the uses of the congregation. He bought almost everything in sight at the prices asked, and then looked about for something more to purchase. There was nothing but the meeting-house, and the lot on which it stood; it had long waited for a purchaser with a full purse, for the site on the corner of Fourteenth and G Streets is in a good neighborhood for business purposes. One of the trustees told Mr. Walsh he could have it for $200,000 cash. It required a few days to perfect the transfer, but recently the deed was put on record, and the price stated at $203,778. The building was erected by an old Scotchman shortly after the capital was invaded and burned by the British in 1814. He owned a foundry in Georgetown, about two miles distant. He had made guns for use in the war, and when the enemy arrived he supposed his foundry would be the first thing wiped out. But the British were so intent upon looting the White House and other official buildings, and in such haste to get away from hostile reinforcements, which existed only in their imagination, that they quite overlooked the iron-foundry. When the proprietor returned with the rest of the panic-striken populace, he was so amazed to find his property intact and himself still rich, instead of ruined, that he attributed it to the special intervention of Providence, and at once voted to repay the Lord with a fine Methodist meeting-house. This he did; and hence the name — the Foundry Church. — *N. Y. Evening Post.*

CHURCH HYGIENE. — In view of the remarks recently published in our columns on the relation of the Church to sanitation, some information appearing in a French journal is not without interest. It seems that the Italian Bishop of Fano has sent out a circular to the priests of his diocese directing that in all churches immediately after feast-days on which there have been very large congregations the floors must be disinfected by means of wood sawdust soaked in a one-tenth per cent solution of corrosive-sublimate. On ordinary days they must be frequently swept, after sprinkling them with water so as to raise no dust, It is further directed that every week, and even oftener, the pews and confessionals must be cleaned with sponges and cloths moistened with pure water, and that every week, and oftener if necessary, the grilles of the confessionals are to be washed and polished, while the holy water receptacles must be emptied every week, or oftener if necessary, and washed with hot water or a solution of corrosive-sublimate. In order that these provisions may be carried out, the Bishop has instituted a service of inspection, and requires the payment of fines into the diocesan treasury for transgression of any of these hygienic rules. The journal responsible for the foregoing expresses the hope that the Bishop of Fano's example will be imitated by Church authorities in other countries. — *Sanitary Record and Journal.*

AN ANCIENT BILLIARD-TABLE. — There is a billiard-table in London at the present moment that can boast of a life-time of two centuries and a long acquaintance with men who have made history. It belonged originally to Louis XIV, passed into the possession of Napoleon I, and now, in its old age, is on exhibition in Soho Square. This celebrated table is smaller than an English table. The body of the table is a block of oak, weighing ten hundredweight, covered with a cloth of electric-blue. The frame of the table is of rosewood, and the six pockets — perhaps the most striking feature of the table — are reproductions in bronze of queer hideous old gargoyles. When the ball falls into the pocket, the lower jaw of the gargoyle drops, and the ball is found in its mouth. It is a clever piece of old mechanism. — *Liverpool Post.*

PROPOSED MONUMENT TO DANTE AT ROME. — The Rome correspondent of the *Pall Mall Gazette* sends this interesting item: "The munificent gift of a monument of Goethe by the Emperor William to Rome has aroused different sentiments in the breasts of Italians, gratitude, and shame that their own greatest poet should have been unrepresented in the capital of the Kingdom. There was a serious project to raise a monument to Dante, but King Humbert's death interfered with the project, which is now revived. By the irony of fate the movement is led by a Clerical. Dante, besides being the father of the Italian language, was the incarnation of the Ghibelline idea, as opposed to the Guelf, or Clerical. Now, to the stupefaction of all, a strong Clerical in the Municipal Council has risen and proposed that Rome erect a monument to Italy's greatest son."

A THREE-WAY BRIDGE AT ZANESVILLE, O. — A unique three-way stone bridge, now building at Zanesville, O., is attracting the attention of a wide circle of engineers. The city is on three river-banks, where the Licking runs into the Muskingum. The new bridge connects the three sections. It is in three parts, each extending from one of the banks of the river to a big three-sided central pier in the middle of the river. The bridge is for the traffic — street-car, wagon and foot — of the population of some 28,000, hence the amount of traffic that passes over the structure is large. All the trolley-car systems of the city are connected with the bridge, and there are double tracks over it. At the centre of the bridge is an arrangement of switches that makes it possible for a car going on to the bridge from either direction to leave it by either of the other arms. — *Exchange.*

NOTES AND CLIPPINGS. 87

TWO serious fires have occurred within a short time in hotels, and the question of protecting hotel guests has, in consequence, come up again for discussion in the newspapers. In the case of the Park Avenue Hotel, which was built, thirty years ago, for a fireproof structure, and was well supplied with brick partition walls, the fatal defect seems to have been in the windows. Those on the side toward Park Avenue gave way immediately before the flames blown across the street from the burning armory building on the other corner, and the curtains, furniture and woodwork were soon in a blaze. The windows opening on the interior court were, in their turn, quickly destroyed, on both sides, spreading the fire all over the building, although the floors were of masonry, and a fire originating, let us say, in the basement of the hotel would have had great difficulty in extending beyond the room in which it originated.

THIS has been the history of so many destructive conflagrations, particularly those in buildings intended to be fireproof, that experts have long agreed that no structure in a closely-built city can be considered even approximately secure against fire, so long as it is provided only with ordinary windows. Shutters, of iron, or of wood covered with tin, will protect windows if they are used; but, in practice, such shutters are out of the question for a hotel, and the only resource available in their place is the use of wired glass. That such glass, if set in metal sashes, and these in metal frames, will keep out fire as effectually as ordinary shutters, has been many times demonstrated, and, if it were not for its unattractive appearance, and its disposition to crack over the wires, the wired glass would be used very extensively, on the advice of architects. The latter, however, are obliged to consult the wishes of their clients in regard to the appearance of their buildings, as well as in regard to its security from fire, and clients who are satisfied with a network of chicken fencing in their front windows, diversified with cracks and bubbles, are rare. Nevertheless, the protection which it affords is so valuable that, if means could be found for making it even tolerably ornamental, its use would be greatly extended; and it does not seem impossible that such means might be found. Some of the glass set in small pieces in copper bars is extremely pretty, besides being nearly as fireproof as the wired glass; and, if manufacturers were disposed to take up the matter, there are plenty of architects who could furnish designs for imbedding in the melted glass an ornamental pattern in wire. In this, or some similar way, using also metal-covered doors and metal trim, hotels could be made really fireproof; and it does not seem unreasonable to suggest that the next amendment to the Building Laws might well take the form of a prohibition of the use of wooden window frames or sashes, or of glass in pieces of more than nine square inches, in any outside or courtyard wall of any hotel. That there would be resistance to such an enactment from the proprietors of stores on the street floors of hotels, and, possibly, from hotel landlords and their guests, is certain; but the latter would soon become accustomed to the change, and would probably find æsthetic attraction, as well as consciousness of safety, in the subdivided glass, and the objections of the former should not be considered in comparison with the safety of the hotel guests whose lives are imperilled by every sheet of plate glass in the building to which they entrust themselves.

A CASE heard in London, on appeal from the decision of a District Surveyor, has a considerable technical interest. Every one has heard of the Rowton Houses in London, where poor people are lodged and fed at a cheap rate, very much as they are in the Mills Hotels in New York. The architect of one of the houses, now in process of erection, designed a geometrical staircase, consisting of steps and landings of artificial stone, made with a core of "breeze" and Portland cement, surrounded with a finishing layer of cement and sand, and containing iron angle-bars, or, rather, bedstead-irons, in each step, the steps and landings being wedged into the wall at one end, but unsupported at the other, except that each step was notched on the one below. The District Surveyor objected to this construction, and directed that a steel or iron string should be put under the outer end of the steps, and a beam under the landings. This order was not obeyed, and, on his rejecting the staircase, an appeal was taken, as provided by the law. The Tribunal of Appeal is composed of experts in construction, and, after hearing a great deal of evidence on both sides, unanimously decided that the staircase was defective, and that the order of the District Surveyor should be carried out.

THE reasons given for this decision are instructive. The Tribunal was of opinion that a staircase of the same form, if made with concrete of uniform quality, would be safe; but the combination of a core of the soft and unreliable coke-breeze with an outer shell of hard concrete, of granite chips and cement, they thought likely to cause cracks, through the unequal shrinkage of the two kinds of material, and it appeared that in other staircases, built in the same way, transverse cracks had already shown themselves. The angle-irons were considered by the Tribunal to be of very doubtful value. The architect thought that the concrete adhered perfectly to them, although, instead of new angle-irons, old bed-irons, which had once been japanned, were used; but the Tribunal believed that the tendency of such irons to start a seam in the concrete in the direction of their surfaces was a source of danger, and that wires were to be preferred. A calculation of the strains and resistances of the steps was made, regarding the steps as independent cantilevers, from which it appeared that, when covered with a crowd of people, the tensile strain on the upper part of the step would be one hundred and eighty pounds per square inch, while the safe resistance of the concrete would be only one hundred pounds to the square inch. We should ourselves think one hundred pounds per square inch much too large an estimate of the safe resistance of concrete made with such a miserable material as coke-breeze; but, on the other hand, it is rather absurd to calculate a geometrical staircase, each step of which rests for its whole length on the step below, as a succession of independent cantilevers. However, the Tribunal, on inspecting the staircase in question, after a test had been made by loading it with brick to an extent only a little greater than the actual weight of a crowd, found that one of the joints between a step and a landing had opened throughout its whole length, probably through the crushing of the soft interior mass under the combined effect of the dead weight and the torsional strain, and its conclusion, that the margin of safety allowed was insufficient, seems to have been justified.

IT is fair to say that the investigation, although it resulted in the rejection of the architect's appeal, cast no discredit on him. The District Surveyor and the Tribunal concurred in praising warmly the work in general, and the question in regard to the stairs was simply a difference of opinion between two experts, carried to other experts for decision. The District Surveyor, Mr. Crow, in particular, showed not only thorough knowledge and excellent judgment in the matter, but a courtesy to his brother-architect which deserves commendation. Although he believed, on theoretical grounds, that the stairs, which were four and one-half feet wide, were unsafe, he went with the architect to see similar stairs, built in another district; and it was not until they had both found in these open joints between the steps and the landings that he gave notice that in

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

the new building he should require the outer ends of the steps to be supported.

ONE of the most unprovoked and malicious strikes of recent years has been in progress in Boston this week, but is now thought to be settled and declared "off." The source of the trouble is to be found simply in a demand made, some weeks ago, upon a large transportation company, which has many offices throughout the country, that it should refuse to accept for transportation goods made by non-union workmen. The officers of the transportation company replied that, while in all other points they were ready to accept the terms of the teamsters' union, they could not comply with this demand, for the reason that they were under contract with shippers of merchandise all over the country to receive and transport goods offered them, and they could not refuse such goods without a violation of their contracts which would involve them in ruinous suits for damages. This explanation would seem satisfactory to reasonable persons, but the agitators chose to reject it, and declared a strike against the transportation company. This strike was a failure, the company easily finding new men to drive its teams, while the Boston police showed admirable efficiency in suppressing the attempts of the strikers to assault the new men. As might have been expected, the leaders of the demonstration saw at once how the newly constituted civic conferences and conciliation committees could be utilized to advertise them, and telegrams, signed with their distinguished names, and addressed to Senator Hanna and other prominent persons, were duly communicated to the newspapers. The Secretary of the conciliation committee even came to Boston, but, after examining the affair, discreetly went back again.

AFTER a week or two of silent preparation, the "strike committee" executed its next manœuvre, which consisted in ordering all freight-handlers, railway-men, teamsters and others to refuse to unload, handle or touch any merchandise brought or offered to them by the offending transportation company. As was undoubtedly expected, the railway freight-handlers who first obeyed the order were immediately discharged, and a general strike of all teamsters and freight-handlers was ordered, to compel the railway-companies to reinstate them. It is fair to the employés of the railways to say that they obeyed the order to strike unwillingly and reluctantly, but the terrors which the union despots are enabled, mainly through the cowardly truckling of politicians, to hold over workingmen prevailed over the natural loyalty of railway servants to their road, and the strike soon affected all the railroad freight-yards in the city. The President of one of the roads gave his men three days to return to work or be discharged, and had the satisfaction of seeing them come back rapidly, and it is probable that the railways suffered very little by the demonstration; but, as is usual in such cases, and as was undoubtedly foreseen, multitudes of innocent and peaceable people were put to annoyance and expense. As the drivers of coal-wagons joined the strike, little or no coal could be delivered, and some small manufactories, to say nothing of the elevators in some buildings, had to suspend operation. In the same way, as materials could not be delivered, building-operations in the city were stopped, and many mechanics were thrown out of work. As is well known, building workmen in Boston never strike, their differences with their employers, when they have any, being settled by a committee of arbitration, so that their enforced participation in a contest in which they have not the smallest concern was particularly vexatious. That the strike must ultimately fail was evident, not only on account of the preposterous nature of the demand on which it was based, but because of the ease with which new men could be found to take up the simple and well-paid duties of freight-handling; and it may be hoped that the people of Boston, who are not so easily deluded in regard to labor matters as they were a decade ago, will take the opportunity to record emphatically their opinion of the desperate attempts which labor agitators have been making for the past two or three years, to shut out from all markets, and from all lines of transportation, merchandise not bearing the union stamp; that is, to reduce all American industry to slavery under the meanest, most cruel and most corrupt tyrants that ever cursed mankind.

A COMPOSITOR'S unfortunate blunder in our last issue must have given the impression that, like Tennyson's brook, our publication of "*The Georgian Period*" was to "go on forever." We will try to correct this impression by declaring that the Part that was published last week is the first Part of the third and final Volume, not, as was printed, "the first Part of five Volumes."

WE suppose that it must be the same Alexandre Sandier, well-known and beloved of many New York architects of the elder generation, who is now at the head of the national porcelain manufactory of Sèvres, and his friends in this country will be interested to hear of the porcelain tower which he proposes to erect in the park of Saint-Cloud, on the site of the "Lantern of Diogenes," which stood in the park until the destruction of the palace by the Germans in 1871. The tower is to be twenty-six feet in diameter and about one hundred and fifty feet high, and is to be entirely covered with decorated porcelain, representing the legends of the Forest of Saint-Cloud, with borders and ornaments taken from the animal and vegetable life of the region. The general ground color is to be white, or nearly so, the decorations being in their natural tints. Those who know M. Sandier's reputation as an artist will be impatient to see this remarkable work completed; but, as thirty thousand pieces of porcelain will be required, and the furnaces of the manufactory can contain only a limited number, it will be at least five years before the materials will be ready. In 1907, however, the Director hopes to be able to begin the work of construction, and the neighborhood of Paris will then be enriched with what is sure to be one of the most beautiful, as well as one of the most curious, of modern monuments.

IT is not impossible that this new undertaking, coming so soon after the extensive use of decorated earthenware in the front of the large Palace of Fine-Arts in 1900, indicates a renewed movement in France toward the use of colored materials in architecture which is of great significance. Since Garnier's well-studied, but rather timid attempt at polychromy with colored marbles in the front of the Opéra, little use has been made of color as an architectural resource in France, except in connection with restaurants or theatres. The polychromatic treatment of the latter has not, as a rule, been very successful, and the decision of the architects of so monumental a building as the large Fine-Art Palace to introduce a frieze in colored porcelain as a background for the capitals of their colonnade was received by the profession with many misgivings. The result, however, amply justified the innovation, and there was, perhaps, no architectural detail in the Exposition so interesting, as a suggestion of possibilities in the way of heightening and extending architectural expression, as the soft, pinkish band of decoration behind the upper portion of the colonnade, so little detached in color from the general tone of the wall that many people never noticed it until it was pointed out to them, yet giving a relief to the beautiful shafts and capitals, and, particularly at a distance, a certain mysterious charm to the effect of the colonnade, which must have struck all architects as affording a promise of new and lovely effects for artists capable of dealing with them. This frieze, we believe, came from the Muller manufactory, and if the Sèvres porcelain is as successfully applied to architecture, which M. Sandier's skill renders more than probable, the architects of the next decade will have a new field open to them.

THE Sixth International Congress of Workingmen's Dwellings will be held in Düsseldorf, beginning June 15, 1902, and continuing five days. The subjects to be considered are the influence of value of land, cost of construction and taxes upon rents; mutual assistance among those in need of dwellings, in the form of coöperative building societies and similar associations; and the effects of the intervention of the public authority in promoting the construction of such dwellings. The members of the Congress will make excursions to the great Krupp Colony, at Essen; to the houses of the Aders fund, and the Society for Savings, at Düsseldorf; and to similar groups at Munich, Cologne and Runscheid. The Secretary of the Committee of Organization, to whom communications should be addressed, is Professor Dr. H. Albrecht, Gross-Lichterfelde, Schillerstrasse, 11, Berlin. The subscription is ten marks, which should be sent to the Kasse A, Deutsche Bank, Manerstrasse, 29-32, Berlin, West. Inquiries in regard to accommodations in Düsseldorf during the time of the Congress may be addressed to Hugo Stangen, Unter den Linden, 39, Berlin, N. W. It is provided, very thoughtfully, that workingmen who are directors or inspectors in any workingmen's building society of general interest, if their application is made to the Secretary before June 15, may be relieved from payment of the subscription.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — V.

IN designing plate-girders there are several dimensions that must be decided by careful calculations, and there are likewise one or two details which must be carefully observed and analyzed. The span of the girder is fixed by the plan of the building, and to a certain extent the depth is likewise limited by the elevations. The depth of a plate-girder, however, should never be less than one-twentieth of the span, and when it is absolutely necessary to make the depth less than the minimum of one-twentieth, the deflection of the girder under the load should be figured, and if it is found excessive, the unit fibre-stress should be diminished by increasing the flange-area.

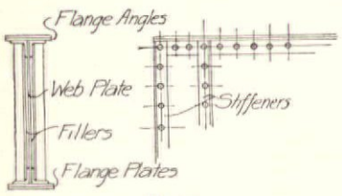

Fig. 25.

The structural features of a plate-girder are the upper and lower flanges, or chords, as they would be called if the web were built up of structural members instead of a solid plate, and the web-plate, all of which is clearly designated in Figure 25. The flanges are essentially the members that resist the bending-stress, while the web-plate is the member that resists the shear due to the loads, and thus transmits the stress from the top and lower flanges. Since the web-plate is responsible for the shear, and as economical consideration in the manufacture of the plate-girder prohibits making this member of different thicknesses of plates throughout its length, the plate must be proportioned for the maximum shearing-stress. The maximum shearing-stress in any simple beam is always at the points of support, or abutments, and is, consequently, equal to the greatest reaction at the ends of the girder; the greatest reaction being the vertical shearing-force acting through the web-plate, it is necessary to obtain enough metal in the section of the plate to resist the shearing-force to which it is subjected. The width

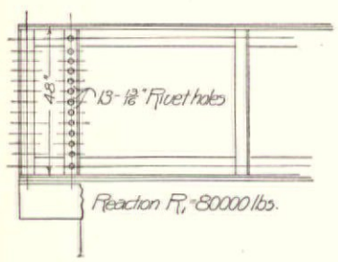

Fig. 26.

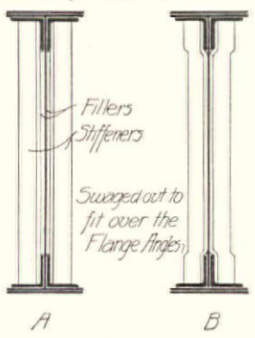

Fig. 27.

of the web-plate having been assumed, it is necessary, in order to obtain its net sectional area, to deduct all of the rivet-holes in a straight line through the end of the plate. The net sectional area cannot be found directly because the thickness is, as yet, undetermined, but the net depth may readily be determined by deducting from the width of the web-plate the product of the diameter of the rivet-holes by the number in the straight line. If this net depth is then multiplied by the safe unit shearing-stress of structural steel, usually taken at 12,000 pounds, the strength of the web-plate, if made 1 inch in thickness, is obtained. When this result is divided into the amount of the greatest reaction, or greatest vertical shear, the thickness of the web-plate required for the particular case will be determined. This can be readily stated in simple formula as follows: $t = \frac{R}{D - (d\,n)\,s}$, in which t equals the thickness of the web-plate to be determined, D equals the depth of the web-plate in inches, d equals the diameter of the rivet-holes, n the number of holes in a straight line, while s equals the safe unit shearing-stress of the metal, usually taken at 12,000 pounds, and R equals the greatest reaction, or the greatest vertical shear upon the girder. The results of this formula can, however, only be used when the required thickness is found to be at least $\frac{5}{16}$ inch, for thinner plates than this have been found, in time, to wear oval at the rivet-holes, and be subjected to buckling, which it was impossible to avoid.

Example. — The details of construction at the end of a plate-girder are shown in Figure 26, and it is desired to find the thickness of the web-plate.

Solution. — From the formula as previously given

$$t = \frac{R}{D - (d\,n)\,s}$$

and in this case D equals 48 inches, $d\,n$ (equals $\frac{13}{16}'' \times 13$) equals 10.56, s, as shown, equals 12,000, and R, as seen from the figure, amounts to 80,000 pounds. By substituting these values in the formula, $t = \frac{80{,}000}{(48 - 10.56) \times 12{,}000} = .18$ inch, or the theoretical thickness of the web-plate. This dimension being less than $\frac{5}{16}$ inch, the web-plate, for practical reasons before mentioned, must be made the minimum allowable thickness. The web-plate, owing to its extreme thinness and great width, is liable to cripple and buckle under the vertical loads which it supports, and it is, consequently, necessary to stiffen the plate by riveting at intervals angles which are usually placed back to back, one on each side of the plate. There are two methods commonly employed of constructing this detail, and they are shown in Figure 27. The construction shown at A is the one usually employed, as it requires less labor, though more material, than the design shown at B. It is possible to do without stiffeners when the depth of the girder is small by thickening the web-plate, but this is seldom done, and angle stiffeners must be provided if the shearing-stress exceeds the value of s as given in the following formula: —

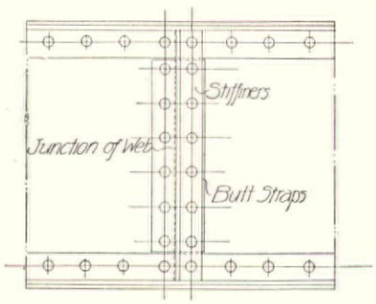

Fig. 28.

$$s = \frac{12{,}000}{1 + \frac{h^2}{3{,}000\,t^2}}$$

in which h represents the depth of the web between the flanges of the girder and t the thickness of the web-plate, both of these values being expressed in inches. Some engineers limit the use of stiffeners to plate-girders having a greater exposed depth of web-plate between the flange-angles than eighty times the thickness of the plate. In all cases, whether stiffeners are used throughout the length of the girder or not, they must be provided at the ends of the girders over the supports, and at all points on the girder where a concentrated load is located.

The stiffeners at the end of a plate-girder are always proportioned so that they will have sufficient sectional area to resist the amount of the reaction, and the usual safe allowable unit compressive strength upon such stiffeners is taken at 12,000 pounds. There is no theoretical rule by which the stiffeners can be spaced throughout the length of the girder, though it is the usual practice to place them at a distance apart equal to the depth of the girder where such a distance does not exceed 5 feet; where the girder is deeper than this the stiffeners are placed at this maximum distance. The sizes of the stiffeners are not usually determined by any calculation, and in actual practice they are made usually of $2\frac{1}{2}'' \times 2\frac{1}{2}'' \times \frac{5}{16}''$ angles for girders up to 4 feet in depth, and of $3'' \times 3'' \times \frac{5}{8}''$ angle for girders over 4 and less than 5 feet in depth. They could be proportioned to resist the vertical shear at the point at which they occur; this is not customary, however, and the sizes of stiffeners mentioned above are commonly employed.

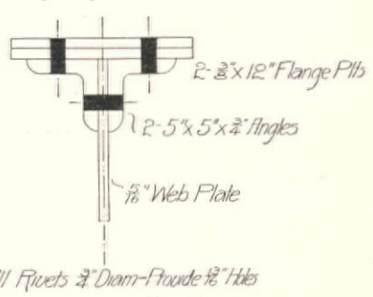

Fig. 29.

Where plate-girders are of great length and considerable depth it is impossible to obtain the web-plate in one piece, and, consequently, it is often necessary to splice this plate. Such a splice should always occur, where possible, at the point of least shear, which in a girder uniformly loaded is at the centre, and

[1] Continued from No. 1366, page 69.

it is usual in making such a splice to place the joint adjacent to a set of stiffeners. The two pieces of the web-plate abut against each other, and are reinforced on each side by butt-straps. These are usually made the same thickness as the flange-angles, and take the place of a filler underneath the stiffeners, as shown in the detail, Figure 28. Where the splice is made at the point of no shear, only sufficient rivets are required to hold the plates in position, and it is usual to pitch the rivets at the maximum allowable pitch, which is 6 inches.

In proportioning plate-girders to withstand transverse stress, it is not the practice to figure the moment-of-inertia, or section modulus of the section, for a plate-girder is regarded as a Pratt truss, the web-plate taking the place of the diagonal and vertical members common in such a truss. Considered in this way, the resisting-moment of a plate-girder is equal to the moment of the tensile or compressive strength of the upper and lower flanges, one about the other; that is, under any transverse stress the lower flange tends to tear apart with a leverage around the upper flange, as a centre-of-moment. From this the resisting-moment of a plate-girder, or M_1, equals $S\,D$, in which S equals the allowable tensile stress of the metal, and D the depth of the plate-girder. The value of S in the formula is equal to $A\,s$, or the allowable unit stress by the net area of the flange, while D is the theoretical depth of the girder taken from the centres-of-gravity of the flanges. The allowable unit stress, or s, adopted for plate-girders used in building-construction is 15,000 pounds, though, where economy demands it, 18,000 pounds may be used with safety. In figuring the area of the flange, or A, many engineers consider only the combined net section of the flange-plates and angles, while others, less conservative, consider one-sixth of the depth of the web-plate in calculating the area of the flange. In either case the area of the rivet-holes cut by a vertical plane must be deducted from the gross sectional area in order to obtain the net sectional area.

While, theoretically, the depth of the girder is the distance from centres-of-gravity of the flanges, in practice the depth of the girder is commonly taken as the width of the web-plate, or approximately the distance from back to back of flange-angles. Since M_1 equals $S\,D_1$ as previously explained, M_1 equals $s\,A\,D$ also, or by transposition, $A = \frac{M_1}{s\,D}$; that is, the net sectional area required in a plate-girder is equal to the resisting-moment at that place divided by the product of the allowable unit stress by the depth of the girder, and in applying the formula the resisting-moment required, or M_1, is obtained in foot-pounds, and the depth of the girder, or D, is designated in feet.

Example. — Determine the net sectional area for a girder having a span of 50 feet, and a depth of 4 feet, when loaded with a uniformly distributed load of 4,000 pounds per lineal foot.

Solution. — W equals $4{,}000 \times 50 = 200{,}000$, M equals $\frac{W\,L}{8}$, or $\frac{200{,}000 \times 50}{8} = 1{,}250{,}000$ foot-pounds. M equals M_1, and A equals $\frac{M_1}{s\,D}$, or $1{,}250{,}000 \div 15{,}000 \times 4 = 20.8$ square inches, which is the required flange-area. In order to provide for this area, assume the flange section shown in Figure 29, which consists of two $\frac{3}{8}'' \times 12''$ flange-plates, two $5'' \times 5'' \times \frac{3}{4}''$ angles, and one-sixth of the $\frac{5}{16}''$ web-plate.

The combined gross area of these rolled shapes is as follows: —

Two $\frac{3}{8}'' \times 12''$ flange-plates	9.	square inches.
Two $5'' \times 5'' \times \frac{3}{4}''$ angles	14.22	square inches.
One-sixth of web-plate	2.5	square inches.
Total gross area	25.72	square inches.

It will be observed from the figure that 3 rivet-holes must be deducted, and their area, provided $\frac{3}{4}$-inch rivets are used, and the hole is made $\frac{1}{16}$ inch larger than the rivet, is as follows: —

Two rivets in vertical position $= 2 \times \frac{13}{16} \times 1\frac{1}{2}$	$= 2.436$
One rivet in horizontal position $= \frac{13}{16} \times 1\frac{13}{16}$	$= 1.469$
	3.905

Deducting the area of the 3 rivet-holes from the gross sectional area of the flange gives $25.72 - 3.905 = 21.815$, or the area of the assumed section. This is slightly greater than the required flange-area, and, consequently, the section can be adopted for the girder n question.

The single web-plate girder shown in Figure 27 is not always used, for in some cases the double web, or box, girder, as designated in Figure 30, is adopted. The principal disadvantage in the use of the single-web girder is on account of its lack of lateral rigidity, and its liability to failure from sidewise deflection. The box-girder should always be used where there is a great length of span, and where wide flange-plates are necessary in order to obtain lateral stiffness; the great disadvantage

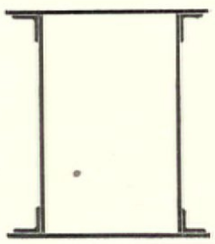

Fig. 30.

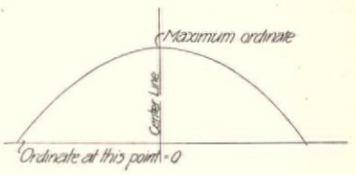

Fig. 31.

in the use of box-girders consists in the fact that they are difficult of access for inspection and painting. Where a single-web girder is not held in position laterally, the width of the flange-plate should be equal, at least, to one-twentieth of the span. If such a proportion does not exist, the sectional area of the upper flange should be increased by the following formula: —

$$A_1 = A\left(1 + \frac{l^2}{5{,}000}\right)$$

in which A_1 equals the necessary gross sectional-area in inches required in the top flange of the girder; A equals the gross area in inches required in the top flange of the girder when the vertical moment alone is considered, and l equals the quotient obtained by dividing the length of the span in inches by the width of the flange, likewise in inches.

As previously explained, when a beam is uniformly loaded, the bending-moment upon it may be represented by a parabola, and as the flange-area is directly proportional to the bending-moment, the flange-area throughout the girder may likewise be represented by a parabolic curve. By observing this curve, as shown in Figure 31, it will be noted that it has an altitude or ordinate of zero at the abutments, and rises to a flat curve at the centre of its length where the greatest ordinate occurs. This would show that practically a flange-area of zero is needed at the abutments, while at the centre of the span the maximum area is required. Where, therefore, a girder is proportioned with a number of flange-plates, it is usual to extend these flange-plates only so far on each side of the centre of the girder as may be required. The greater the number of flange-plates, the more nearly may theoretical economy in the design of the girder be obtained. It is customary to extend the flange-angles throughout the girder, and where the girder lacks lateral support, it is the best practice to carry the first flange-plate the entire length of the girder, as well as the flange-angles. The remaining flange-plates may be reduced to within 2 feet of their theoretical length, a foot being necessary on each end over and above the theoretical length in order to provide for riveting. The theoretical length for the flange-plates on any girder supported at both ends and uniformly loaded may be

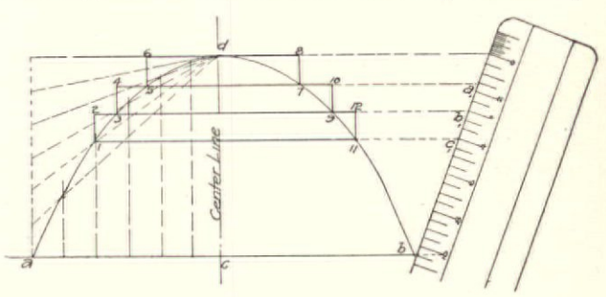

Fig. 32.

determined by means of the diagram shown in Figure 32. In this figure lay off the line $a\,b$ equal by any scale to the span of the girder, and make the length of the centre ordinate $c\,d$ equal by any scale to the maximum net flange-area, divide the ordinate at a into any number of equal parts and likewise the distance $a\,c$ into the same number of parts, extend lines from the divisions upon the vertical line at a, radiating to the point d,

and draw from the divisions upon the horizontal line $a\,c$ the ordinates as shown; through the points at which the ordinates intersect the corresponding radial lines draw the curve which is a parabola as designated. By laying any scale diagonally across the drawing, as shown, so that the number of divisions upon the scale equals the number of square inches in the combined net flange-area, the areas of the several flange plates and angles may be laid out; these areas are obtained by counting off a number of divisions as at a', b', c', equal, respectively, to the number of square inches in the net area of the several flange-plates. Extend from the points a', b' and c' the horizontal lines designated, and from the point of intersection of these horizontal lines with the parabola draw the heavy vertical lines to the next horizontal line above, as shown at 1–2, 3–4, 5–6, 7–8, 9–10, etc.; then the length of the several flange-plates may be found by scaling the distances 6–8, 4–10, 2–12, with the same scale to which the span of the girder $a\,b$ was laid off. These lengths are the theoretical lengths of the flange-plates, and a foot at each end must be added in order to determine the length of flange-plate that should be used. Where it is not desirable to use the graphical method there is a formula by which the length of the flange-plates may be calculated where the girder is uniformly loaded. This formula is

$$L_1 = L\sqrt{\frac{A_1}{A}}$$

in which L_1 equals the theoretical length in feet of the flange-plate in question; L equals the length of the girder from centre to centre of supports, in feet; A_1 equals the net sectional area of all of the flange-plates counting from the outside of the girder and including the flange-plate in question, while A equals the total net flange-area.

Example. — Assume that a plate-girder having a span of 60 feet has a net flange-area equal to 40 square inches, and that the flange is composed of two flange-angles and four $12'' \times \frac{5}{8}''$ plates, each of which has a net flange-area equal to 6.25 square inches; determine the length of the four flange-plates.

Solution. — Since a girder having such a narrow flange lacks lateral stiffness, the flange-plate next to the flange-angles should extend the full length of the girder; by substituting in the formula, the length of the outside plate is equal to L_1, or

$$60\sqrt{\frac{6.25}{40}} = 23.40 \text{ feet};$$

the length of the flange-plate next to the outside one is equal to L_1, or

$$60\sqrt{\frac{12.50}{40}} = 33.60 \text{ feet},$$

while the third flange-plate is equal to L_1, or

$$60\sqrt{\frac{18.75}{40}} = 40.80 \text{ feet}.$$

These lengths, as previously explained, are the theoretical lengths, and must be increased at least 1 foot at each end.

Where a girder is loaded with a number of concentrated loads the flange-plates can also be stopped off and a saving in

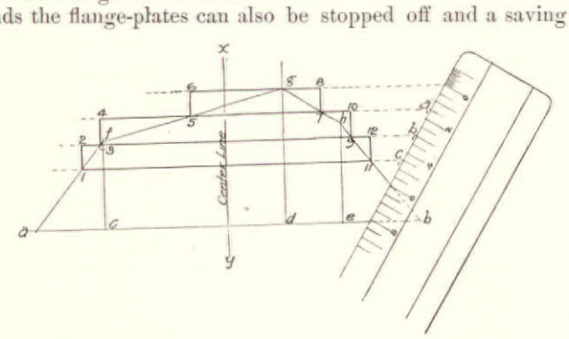

Fig. 33.

metal and riveting thus instituted. The method commonly employed is shown in Figure 33 and consists of laying off the line $a\,b$ equal by any scale to the span of the girder and locating accurately upon it the concentrated loads, which may be of any number and amount, as shown at c, d and e; upon ordinates located at these points the amount of either the bending-moment or the net flange-area required at the several locations must be laid off, as at c-f, d-g, e-h; then by connecting a-f, f-g, g-h and h-b, a true diagrammatic representation of the bending-moment is obtained; draw the indefinite horizontal line through g and lay off with the scale as shown, and as previously explained in connection with the uniformly distributed load, the net sectional area of the flange plates and angles; these divisions are made as at a_1, b_1 and d_1, and the horizontal lines extended from these

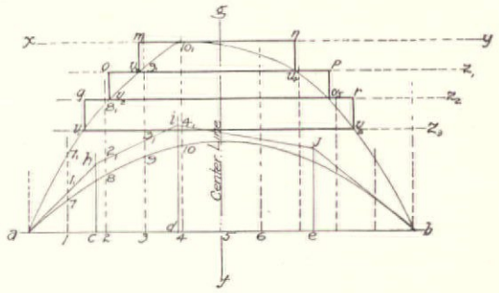

Fig. 34.

points as shown. Where these lines intersect the funicular polygon $a\,f\,g\,h\,b$, as it is called, draw the vertical lines as shown at 1–2, 3–4, 5–6, 7–8, 9–10, 11–12, and by measuring 6–8, 4–10, etc., the theoretical length of the several flange-plates is determined, the measurement being made as before, with the same scale to which $a\,b$ was laid off. These flange-plates must be located properly with reference to the centre line $x\,y$, and the location may be determined by scaling from the diagram.

The graphical method for determining the length of flange-plates where the girder supports both a uniformly distributed load and several concentrated loads is designated in Figure 34. This diagram is a combination of the methods employed for the uniformly distributed load and the concentrated load. It consists of laying off to scale the span of the girder as a, b, and upon the centre line $g\,f$ marking to scale a distance equal to the bending-moment caused, or the flange-area required, by the uniformly distributed load only; through the points a and b, a parabola is drawn as described in connection with Figure 35; from the points c, d and e, which are the locations of the three concentrated loads upon the girder, ordinates are erected, and upon these ordinates the bending-moments, or flange-area, due to the concentrated loads alone are laid off, as at c-h, d-i and $e\,j$, using the same scale as in measuring the parabola. The diagrammatic figure consists of the parabola representing the uniformly distributed load, and the funicular polygon representing the concentrated loads; both together express the distribution of the bending-moments upon the girder. The combined effect of the two loads is obtained by dividing the span $a\,b$ into any number of equal parts and from these divisions, as 1, 2, 3, 4, 5, etc., extending the vertical ordinates, lay off the distances 1–7, 2–8, 3–9, 4–10, etc., from the points 1_1, 2_1, 3_1, 4_1, respectively, obtaining the measurements 1–7_1, 2–8_1, 3–9_1, 4–10_1, etc.; from these points draw the irregular curve as designated; through the highest ordinate of this curve draw the horizontal line x-y, and by placing the scale as designated lay off the divisions representing the net sectional area of the flange-angles, as explained in connection with Figures 36 and 37, and as shown in this diagram at z_1, z_2, z_3; from these points draw the several horizontal lines designated, and where they intersect the irregular curve, as at v_1, v_2, v_3, v_4, v_5, v_6, etc., draw the short heavy vertical lines upwards as designated; then by measuring the distances m-n, o-p, q-r, etc., the theoretical length of the several flange-plates may be determined. As explained in connection with the diagram for determining the theoretical length of the flange-plates where the girder supports several concentrated loads, the flange-plates in this case must be placed with relation to the centre line as called for by the diagram.

The several principles and usual methods for proportioning and designing plate-girders have been given; the rivet-spacing, however, is important, and will be explained in the next article, in connection with the strength of rivets. M. M. Sloan.

[To be continued.]

Ruskin Memorial in Poets' Corner. — The work of the committee formed for the purpose of placing a memorial of John Ruskin in Westminster Abbey has been accomplished. The memorial takes the form of a bronze medallion. The sculptor was the late Mr. Onslow Ford, R. A. The place assigned to the memorial by the Dean and Chapter is in Poets' Corner, immediately above the bust of Sir Walter Scott. — *Exchange.*

MODERN OFFICE-BUILDINGS.[1]

SOME of Mr. Bolton's remarks indicate that he recognizes, what other keen observers have already recognized, that the high steel-skeleton office or hotel building is not simply an architectural problem, but a problem in which the architectural treatment is but one of the coördinate parts of the design.

The architectural treatment is not and should not be considered as the controlling factor — though it generally is — in the design of this modern embodiment of concentrated facilities for administrative business or communistic living.

In buildings of this character a very little thought will be required to perceive that the architectural design is not the controlling factor, and therefore should not be allowed to fix the conditions, to which all other parts of the design should conform. To illustrate this idea: The architectural design can be changed, almost an infinite number of times, without the mechanical-engineering essentials being changed at all, and with only such changes in the structural design as may be required locally by the changed architectural disposition of the materials composing the walls, etc. If the truth of this proposition is recognized, it is evident that no extended argument is required to show that the present method is wrong, in putting in the hands of the individual designer of the façade the final decision on all matters of design; and the truth of this proposition can be admitted and acted upon without in any way belittling or making light of the architectural problems, which are of great importance, and should only be entrusted to broad minds and capable hands. For as long as appearances continue to be a factor in human affairs, and as long as beauty of line and form appeal to our sense of intellectual fitness, just so long will the architectural problem be worthy of the most careful consideration.

The recognition of the fact that the architectural part of high-building construction is not the governing factor gives no excuse for slighting this part of the design, but it should be also recognized that the architectural problem, in its specific relation to high-building construction, can be worked out to a rational solution only when the limits which bound it are defined by the factors which actually should control the design as a whole. High steel-skeleton building-construction may be defined as an engineering work with an architectural accompaniment.

It is perhaps already evident that in order that each of the elements entering into the design as a whole be given proper recognition, and its due value as a factor, the chief designer should be a man capable of judiciously passing upon the claims of each of these elements to precedence. Experience has shown that the man who owes his training exclusively to the art-school and its influences cannot or will not consider the engineering side of the problem. The men who spell their art with a capital A deplore science, as a necessary evil, which disturbs their mental repose; and, if not as an evil, then as a bore, which interferes with and places practical obstacles in the way of their flights of fancy. Mathematics and science are looked upon by men of this type as matters of formulas, rule-of-thumb and mechanical routine, a matter to be learned out of a book, which can be mastered in about the same way that one learns to recite a piece of verse or prose, or as one learns a trade. Men of this type do not think that imagination enters into the study or practice of science, and particularly the science of engineering, and look upon themselves as the only rightful possessors of the wings of flight or imagination. They have no conception of the trained imagination required to comprehend the higher mathematics, nor of the sustained and logical derivatives of the product of thought, obtained from mathematical investigation. Having no appreciation of the intellectual basis of engineering, it is not to be wondered at that they treat the demands of science with scant consideration. It is, therefore, hardly to be expected that the graduate of the art-school only, whose whole mental training has been given up to the study alone of the relative values in the play of light and shadow, the balancing of solids and openings, the study of the appearances of things, or the art of seeming, can be qualified to pass upon problems which deal with realities or things as they are. In works of magnitude, under the guidance of such minds, the structural and mechanical parts of the design are often sacrificed to supposed requirements of art; and the result is an incongruous composite of the total elements of the design, and, necessarily, a failure.

Another type of mind which is unsuited for the position of designer-in-chief is that type which has no appreciation of art and beauty, and has no other "measures" than those of "economy" and "efficiency." This type, while useful in a large way as a counterweight and a standard of comparison, often misses the best solution, or possibly never attains it, in a problem of this character, by the narrow view it takes of the things with which it is not familiar, and, by reason of one-sided training, is not fitted to be an intelligent and impartial judge of the various elements entering into a composite and complex design.

The designer best qualified for this important position of designer-in-chief is evidently one who has a knowledge of the broad essentials and limitations of the various parts of the design, the judicial temperament permitting the balancing of an advantage against a disadvantage, a breadth of mind enabling a comprehensive view to be taken, coupled with courage and decision; with all these qualifications, governed by a broad and catholic love of beauty in all its manifestations — not only of beauty of form and line, which is evident and can readily be comprehended, but of the more subtle beauty of science and its results.

This combination of qualities is not an impossible one, or, in fact, necessarily a very rare one. It is realized, perhaps, more definitely in the scholarly engineer, whose acquaintanceship with facts and laws governing matter is accompanied with a broad knowledge of the fundamental requirements of art, and to him must eventually come the position of master builder.

If the composite design of one of these engineering-architectural problems is analyzed, it will be seen to admit of two main subdivisions:

(1) The engineering design.
(2) The architectural design.

The engineering design can be subdivided into its structural and mechanical components: The structural component, comprising the foundations and superstructure, including the stability of the structure against vibration, wind forces, fire and corrosion. Under the head of structural design should also come the planning of the floor areas and spaces, with all their subdivisions. Usually, the floor-plan is laid out by the architectural designer without reference to the structural design, and this results frequently in poor and expensive construction. The consideration of the floor-plans and the structural design should take place at the same time — and preferably by the same mind, or, at any rate, by minds working in harmony, for the floor-plan and the structural arrangement are truly dependent on each other. The arrangement of the floor is not strictly an architectural problem, though it is frequently considered as such; it is also a scientific one, or one in which all the factors can be determined and balanced one against the other, and an equation arrived at figuratively, from which a result can be obtained which rests upon determined facts, and not upon mere whim, prejudice or predilection. Daylight has a certain carrying and distributing power which does, or should, determine some of the dimensions of rooms.

Transportation facilities and convenience of access determine the local arrangement of the office-areas around the elevators, or, rather, the location of the elevators with reference to the "centre-of-gravity" of the office-areas. The economic location of lavatory-fixtures requires the grouping of these fixtures around common drainage and water-supply centres, which in turn demand certain broad arrangements of lavatory rooms and fixtures, usually not difficult to comply with.

The lighting and heating systems require distributive local centres and sub-centres, which should bear certain relations to the groups of offices and sources of supply.

Not infrequently, the floor-plan is decided upon and then turned over to the structural designer with instructions that nothing can be changed. This results sometimes in the use of structural expedients which are expensive and structurally unsatisfactory, and which could have been avoided by an appreciation of the relative values of each of these matters. The consideration of the scheme, also, from one standpoint only often results in the sacrifice of the best arrangement of the mechanical equipment.

When the planning of the floors and the structural design is under discussion the fireproofing and rustproofing should also be considered. It is not an uncommon thing to find the fireproof covering cut away to get in a door or window frame, or some piping that has been overlooked or not considered when the planning was under consideration, and for this there is no excuse, unless haste in preparing the plans — due to no fault of the designer — is given.

Fireproofing is generally given but scant consideration, and rust-proofing little, if any, and for this neglect no adequate excuse can be given. The fireproofing is seldom considered as a part of the design, but is taken care of by general methods of allowances over the dimensions of the beams, girders and columns. The intelligent designing of fireproofing demands a knowledge of the weakening effects of heat on steelwork. The maximum strength of iron is at about 400 degrees Fahr., and there is a loss of strength of about 1,000 pounds per square inch of section for every increase of 100 degrees in temperature. A knowledge of the rate of transmission of heat through various substances and dead-air spaces, and a knowledge of the resistances of various materials to the action of fire and water, separately and alternately — a little knowledge of these various matters — will be sufficient to show the insufficiency of many of the present methods, and the inadequacy of many of the materials used for this purpose. Porous or semi-porous terra-cotta properly made and burned is probably the best material in use, but, as it is manufactured to-day, it is too thin, and the standard beam-coverings, with a thickness of only 1 inch over the lower flanges of the beams, are absurd, and the column-coverings and the methods of fastening them on the steelwork are but little better.

The question of rust-proofing is seldom considered, and is often entirely ignored. The rusting of iron is such a familiar fact that it is surprising how little attention is paid to it. Millions of dollars are being invested yearly in buildings the durability and stability of which are entirely dependent upon the iron framework, yet, beyond giving the metal-work a coat of paint, nothing is done. The fact that Portland-cement preserves iron from corrosion is now well known, and the chemistry behind this fact should be as well-known. Rust is caused by three factors working together, viz., water, an acid, and oxygen. If these three factors are not allowed to act coördinately, rusting cannot take place. Portland-cement, because it is a product

[1] A letter by William Copeland Furber, M. Am. Soc. C. E., read before the American Society of Civil Engineers, and published in the *Proceedings* of the Society.

of lime, furnishes a base which neutralizes any acid likely to be present under ordinary conditions, and therefore any water which may filter through it can do no harm. This fact is acted upon in the use of steel in the foundations of buildings below the water-line, but little use is made of the knowledge above the cellar-floor.

The mechanical component of the engineering design, comprising the steam-power plant for operating the elevators, the lighting, heating and ventilation systems, and the layout of each of these parts; the lighting-system, consisting of dynamos, distributive wiring and storage-battery; the heating-system, consisting of the distributive piping, etc., with the fans and ducts required to supply the heat and air under pressure, and to remove the foul air; the operating mechanism of the elevators; the water-supply for individual and general uses and fire-protection; the drainage-system, and the telephone and telegraph wire-systems; should all be considered and tentatively laid out before the final plans are decided upon.

The requirements of each of these subdivisions of the mechanical design require most careful study, and, as they are a vital part of the design as a whole, they should be laid out to accomplish the best possible results, and this arrangement adhered to as closely as is permissible with reference to other parts of the scheme. Most of the evils of crowded and unsatisfactory layouts of the mechanical equipments in high buildings are the result of lack of knowledge, on the part of the designer-in-chief, of the conditions of arrangement conducive to the best results. The fact that the equipment can be placed and operated in inconvenient and contracted spaces is also taken advantage of, and the mechanical equipment relegated to such spaces as can be devoted to no other purposes. When the amount of money required to maintain and operate this equipment, and its proportion to the total operating expenses of the building, are considered, no defence can be made of the inadequate facilities usually allowed for its installation.

In the distributive systems of the mechanical plant, the placing of pipes, conduits, etc., in the floors, walls and partitions is frequently not considered in the detail drawings, and is generally merely specified. This neglect sometimes leads to a great deal of trouble and often to the adoption of make-shift methods, which could have been avoided by due consideration being given to the details on the drawings.

The architectural design consists in the main of the treatment of the façade, usually according to, or with the details of, some historic style; the arrangement of the windows, and, in a secondary way, the architectural treatment of the offices. This internal treatment of offices can be said to be independent of the general architectural, structural and mechanical design, and therefore not a factor in the design of the whole, with which only this particular discussion deals.

The arcitectural part of the design can be changed according to the whim or predilection of the designer without materially affecting the other parts of the design. It is therefore evident that with this liberty goes great responsibility. If the design decided upon is one of a possible thousand, and the design is a poor one, the responsibility is proportional to the number of better ways of solving the problem.

A great mistake that many architectural designers make in treating the high skeleton building is in attempting to treat it as a masonry structure. This lack of perception of the limitations of masonry construction leads them to many curious anomalies and absurd results, as, for instance, the placing of a Greek temple on top of a many-storied building, and the employment of brackets, consoles, modillions and other architectura ldetails which once had some function, but which are now, in these buildings, wired or strapped upon an iron framework.

The high skeleton building is worthy of an architectural style consistent with its serious purposes and the dignity of its place in the modern business world, and this style should express the truth of its construction and its purposes, and should not make it masquerade in borrowed clothing, pretending to be a masonry structure, yet violating some of the fundamental principles of masonry construction. Architecture needs the stimulus of new truth and new conditions, and the skeleton building furnishes them.

A CONCRETE COURT-HOUSE.

THE Nassau County Court-house, which has just been completed, is one of the most important buildings ever constructed entirely of cement-concrete. The entire work was constructed under the Ransome system, which consists of reinforcing the concrete with cold-twisted steel bars of great strength, which are placed at proper points, both vertically and horizontally, in the concrete. The general dimensions of the building are 195′ x 95′, in the form of an inverted T. It is two stories in height, 36 feet from the ground to the roof, and the height to the apex of the dome is 65 feet. The general measurements of the court-room are 38′ x 50′ and 18 feet high to the ceiling. It is situated on the second floor, with two jury-rooms and a judge's room in the rear. The foundation-walls, floors, pillars, partitions and dome are of cement-concrete. The building is practically an immense rock, cut and dressed with architectural ornament on the outside and mined inside in the form of rooms. A building of this character represents a class of construction that is certainly ahead of anything known to the building world as regards its fireproof qualities. The records of the great fires of Chicago and Boston have given proof of an unquestionable nature that cement-concrete is as good as any fireproof building-material. The exterior of the new county-court is especially attractive. The concrete is finished in a very satisfactory manner; both smooth and rough surfaces are produced with perfect success. To give the concrete the appearance of rough-dressed stone, it is gone over with pneumatic tools, except on ornamental and fine-dressed work, where hand-chisel is used. The appearance is so perfect that the difference between natural stone and the concrete is hardly distinguishable. The lines representing the joints between stones are made by placing strips of moulding lightly nailed to the inner surface of the mould. They may be arranged in such manner as desired, and of any shape or size to suit requirements. The concrete is then filled into the moulds in the usual manner, and when it is sufficiently set the moulds are removed. This leaves the concrete marked off as if built up with stone. The ornamental work was made from plaster moulds, and each part has imbedded in it the bars of twisted steel, which not only serve to strengthen it, but also afford a means of securing the ornament to the wall in a most satisfactory way. The sharpness of the detail in ornamentation of the most elaborate design is a feature of the work on this building. The court-house is connected by a concrete tunnel with the jail, which was also built according to the Ransome system. — *Stone Trades Journal.*

CORRECTION: THE A. D. CLUB BUILDING.

WE regret sincerely that we were innocently the instrument of doing injustice to the author of this design. We have been advised since publication of our last issue that in the carrying out of his design Mr. Charles K. Cummings, of Boston, associated with himself for this work Mr. J. Harleston Parker, the now senior member of the firm, to whom the entire credit was mistakenly attributed. — EDS.

NOTES AND CLIPPINGS

THE GLASTONBURY THORN. — It is to be hoped that another Glastonbury thorn will be obtained to replace the missed one in South Kensington Gardens, for in the bustle of modern times it is pleasant to be occasionally reminded of the legends and beliefs of our forefathers.

By them it was held that Joseph of Arimathæa struck his travelling-staff at Wearyall Hill, near Glastonbury, where it immediately took root, and annually blossomed at Christmas. In the reign of Queen Elizabeth it had two trunks, but one was destroyed by a Puritan, the other being preserved for a time by a flying chip, which blinded the assailant. The remaining trunk was cut down by another Puritan in the reign of Charles I. Early in the nineteenth century a small flat stone, bearing the inscription of J. A., A. D. 31, was placed to mark the site where the tree grew. Of course, the initials stand for Joseph of Arimathæa, while the date is that traditionally ascribed to his visit. So great was the demand for relics from the Glastonbury thorn that before its destruction many trees had been grafted in the neighborhood. Not only was it noted for its miraculous blossoming; its sprigs and blossoms — about the size of a sixpence — were considered sovereign specifics for avoiding the evil eye, rooting out weeds from corn, and various other evils. Its fame spread beyond the seas, and down to the reign of Henry VIII the Bristol merchants exported these blossoms to different parts of the world. Crowds, too, annually visited Glastonbury down to recent times at Christmas to see the blossoming. A curious story is told in *The Gentleman's Magazine* for January, 1753. Confusion still existed concerning the old and new style, and a vast concourse of people assembled at Glastonbury to see the trees blossom on December 25. No blossoms came on that date, but on old Christmas Day they appeared as usual. — *London Chronicle.*

False Antiques in Europe. — Philip G. Hubert, Jr., narrating in the March *Century* "A Bavarian Bric-à-Brac Hunt," has this prefatory warning concerning the tricks of the dealers: "In the way of carved furniture, I am afraid that there are more fraudulent antiques than genuine in the Paris shops to-day. There is one dealer in particular who, when closely questioned as to the origin of certain Louis XV sideboards and tables he has for sale, will tell you they came from the Château of Chenonceaux, the famous little palace where the fair Diane de Poitiers once lived and loved; and in proof of it he will show you a bill of sale, duly stamped and authenticated, of a certain lot of furniture sold to him in 1863 from the château. Hundreds of persons, doubtless many Americans among them, have bought those Chenonceaux tables and buffets, and have seen that precious document, which, no doubt, is good so far as it goes. Unfortunately, according to a rival dealer, that bill of sale covered only two sideboards and three tables from Chenonceaux, notwithstanding which, Chenonceaux tables and chairs have been pouring forth from the little shop in a steady stream for the last twenty years — enough to freight an ocean steamship. The widow's cruse of oil was nothing to it. I do not doubt that if I were to order fifty Chenonceaux tables to-morrow, the proprietor of the shop would agree, with a twinkle of intelligence, to fill the order within a reasonable time. Some time ago the neighbors of a certain petty furniture-dealer in London complained of the constant pistol-shooting in the tradesman's back yard. Haled before a magistrate, the man testified that he was a reputable manufacturer of "antique" oak chests, and that it was necessary to fire bird-shot at his new chests in order to give them a worm-eaten appearance; which anecdote recalls to me that I once saw in the window of a bric-à brac shop in Strasburg this announcement: 'The Newest Things in Antiquities.'"

Empirical Way of prejudging the Effect of a Monument. — Some time ago the well-known French sculptor Bartholdi described in *La Nature* a simple method of ascertaining what dimensions of a proposed monument will produce the desired effect on a given site. A silhouette of the design is cut from cardboard, either a scale-drawing or preferably a photograph from a scale model furnishing a basis therefor. If this can be tinted so as to give the tone of the material to be used, so much the better. The silhouette is attached to one end of a piece of soft wire, which is wrapped loosely round a cane, umbrella, or other similar support, so that its position may be shifted back or forward at will. On the site of the monument, just alongside where the base will probably come, is placed a vertical measuring rod marked off into prominent divisions. The experimenter takes his position at a sufficient distance to secure a good general view, and brings up to the level of his eye the support carrying the silhouette, aiming as with a gun towards the site. By shifting the position of the silhouette along the support it may be determined after a while where it produces the best effect, considered as furnishing the illusion of the original structure. By there noting the correspondence in height between any given division of the small design — as, for instance, the top and bottom lines of the die — and the feet or yards on the measuring rod, a scale can be established. This scale applied to the drawing or model will show what the sizes of the executed work should be. — *Stone Trades Journal.*

Destruction of Rood-lofts. — The order of Edward for the taking down of roods applied, in the first instance, simply to the removal of the rood figures, *per se*, being afterwards erroneously concluded to extend to the rood-loft, or gallery of access to them. This gallery was formed on the upper beam of the screen, into which the joists of it, with the supporting timbers of the rood figures, were framed, and its either side was defended or fenced in by a parapet along its length, to secure safe passage across. It was this gallery, or passage, to, and as such connected and associated with, the objected-to rood figures that it was the object of the reformers of Elizabeth's time to do away with, as is very clearly and explicitly shown by her order. The indiscriminating ignorance and prejudice of the age, however, failed to distinguish between transposition, "transposed" being the word of the order, and destruction, as it had already done between reformation and abolition, and from the lack of a clear understanding or a wilful misconception of former orders, had both the rood-gallery and its figures pulled down, and were continuing to pull down, the entire upper portion of the screen, extending the demolition in some instances to the entire structure of it, leaving them as that at Southwold, and in a number of other cases, is now seen stripped to their naked framing and entirely denuded of their upper part. To this condition it was not the authorized intention to reduce them. Elizabeth's order clearly defines the extent to which they were to be altered and the mode in which they were to be finished and left after such alteration. The words are as follows: — "It is thus decreed and ordained that the rood-lofts" — roods had already been previously for the most part removed — "as yet, being at this day aforesaid, untransposed, shall be so altered that the upper part of the same with the soller" — an old term for an upper story — "be quite taken down unto the upper parts of the vautes" — vaulting — "and beam running in length over the said vautes, by putting some convenient crest upon the said beam towards the church"; that is to say, the rood-loft or gallery was to be taken down to the beam or cornice above the groined canopy or vault, and was there to be finished with a crest ornament or brattishing, the common mode of finishing such a cornice or termination. — *The Architect.*

An Old-time Organ. — In Clyde, N. Y., a Wayne County village, is the oldest church pipe-organ in the United States. Additional interest attaches to the instrument from the reason that it was the first whose pipes gave music for the worshippers in old Trinity, New York City. The organ is now occupying a place of repose and honor due to the dignity of old age in the chapel of St. John's Episcopal Church. It has had a somewhat remarkable career from the time it came to the New World as a royal gift to the day its place was taken in the country church by a rival of more modern make. The organ was installed in old Trinity as a mark of Queen Anne's special favor to the Englishmen who had made New Amsterdam into New York. The gift was received with the royal command that it should never be sold, but that when the parish could afford a better one it should be transferred to a church which had no organ. After many years the old instrument was set up in Trinity Church, Utica, where it was used for more than two decades. Still honoring the precept of Queen Anne, although times had changed and royal commands had little effect among the people of the new States, the organ was sent here in 1846, and from that date to 1884 it served St. John's Church. Once it had a narrow escape, for the church was burned, but the parishioners bent all their efforts toward saving the organ, and succeeded. When the new instrument was put in position in 1884, the old Queen Anne's gift was removed to the chapel, where for more than ten years its keys have not been touched, but the parishioners prize it highly. The ancient instrument is 8 feet in height, 7 feet in width and 4 feet in depth, with one set of keys and six stops. — *N. Y. Tribune.*

Electroplating Wooden Doors. — A process of covering wooden doors with sheet-metal by means of electrolysis is at present being experimented with at Bridgeport, Conn. The excellent fire-resisting qualities of a wooden door covered with tinplate have long been recognized, since the metal covering prevents the wood taking fire, while the use of wood for the framing avoids any risk of the warping of the door by heat, allowing flames to pass through, as has happened with doors built wholly of iron. A tinplate-covered door has, however, a poor appearance, and is therefore suitable only for workshops and warehouses. By depositing copper or bronze electrolytically, it is hoped to provide doors suitable for buildings of all kinds. The method followed is to place the carefully-finished wooden doors in a hot solution of fossil gum in linseed-oil. This completely closes the pores of the wood with an impervious varnish, so that on transferring the door to the electrolytic bath the solutions are not absorbed. On removal from the varnishing bath, the edges of the door are bound with sheet-copper fixed by cement, and the rest of the door is then covered with a conducting layer of bronze powder, after which the whole is placed in an electrolytic bath, and copper deposited over the whole surface. — *Building News.*

The Illinois Central planting Catalpa Trees. — John P. Brown of Connersville, Ind., Secretary of the International Society of Arboriculture, passed through this city recently on his way to New Orleans. Mr. Brown has been employed by the Illinois Central Railroad to inspect the lands owned by that system in Mississippi with a view to selecting an area suited to the cultivation of catalpa trees. The purpose of this experiment is to raise catalpa trees on some of the unimproved lands of the Company to be utilized in the shape of cross-ties, posts and lumber. The Company has authorized Brown to plant not less than 200,000 catalpa trees, and figures that, in the course of about fifteen years, it will have a most valuable forest, furnishing thousands of dollars' worth of cross-ties, lumber, and posts of various kinds. The experiment has been tried by a number of railroad-companies in the United States. The strongest claim for the catalpa tree is the greater durability of this wood, which is said to outlast anything else in the field. — *Boston Transcript.*

Street Nomenclature in East Boston. — "Monmouth" is a familiar word to the student of Revolutionary history, and this fact was called to Lieutenant-Governor Bates's attention by the writer. "You are evidently not acquainted with East Boston," he rejoined, and then said the early founders of the island city divided the town up into sections; the first section of streets is named after the notable battles of the Revolution; the second section, running at right angles, is named after the generals in the Revolution; the third section is named after the great English poets, with the addition of Homer; the fourth section is named after the great cities of Europe, while the fifth section is named after birds. — *Boston Herald.*

Cataloguing the Papal Art-treasures. — The Pope recently received a petition to encourage the project of making a catalogue of all art-treasures preserved in Italian churches and monasteries, to prevent their being secretly purchased and exported. — *Exchange.*

NOTES AND CLIPPINGS. 95

THE newspapers have commented very generally, although not, in some cases, very intelligently, on General Sooysmith's address, delivered a few days ago before the Chicago Real Estate Association, in which he warned his hearers that many of the great steel-framed buildings, for which Chicago has long been famous, had only a few years of existence before them. Architects generally have long known General Sooysmith's opinions in regard to steel-framed buildings, and accumulating experience has confirmed their correctness; but the warnings, given fifteen years ago, that an improperly constructed steel-frame building would not last more than twenty years, seem much more serious on repetition now, when, if they are well founded, many millions of dollars' worth of property, and, perhaps, many lives, hang by a thread, which may break at any moment, and is sure to break within a very few years. General Sooysmith drew, as he has always done, a sharp distinction between a steel-frame building properly constructed, in which every piece of metal in the main supports is thoroughly embedded in cement, in contact with it, and those in which the metal is surrounded with stone, or brickwork, built up against it, but in such a way as to leave crevices, through which air can circulate. Buildings of the first sort, he said, were good for two thousand years, while, in those of the other kind, unfortunately much more numerous, the metal corrodes with great rapidity under the influence of the moist air in the crevices, and corrosion of one-fifth the substance of the metal of a supporting member at any given point would, in general, cause its failure.

WE do not know what authority General Sooysmith finds for his opinion that iron, even thoroughly embedded in cement, will last for two thousand years in this climate; and, as we have often said, actual investigation on these points is urgently needed; but the fact that neglected iron, exposed to damp air, rusts very rapidly, is well known. In the case of iron bridges, and other structures, the metal of which is visible, and can be cleaned and repainted as soon as it shows signs of rust, engineers usually reckon on an average life of only forty years, yet the air around these is almost always dry, and it is only in clear nights, when the dew gathers on them, and during rains or fogs, that they rust; while the steelwork in a building is not only covered up, out of reach of the scraping and repainting on which the preservation of a railroad bridge depends, but it is sheltered from the drying influence of the wind, at the same time that the air around it is kept saturated with moisture by evaporation from the enclosing masonry, which is always damp, even the dryest winds only removing superficially the water which all brick and stonework absorbs from rain. Moreover, in railway bridges, it is now usual to arrange the structure so as to avoid sudden collapse, by distributing strains, so that one or two overworked members may even given way, without involving the destruction of the whole, as in the recent case of the Brooklyn Bridge; but in buildings this is difficult, as the necessity for large windows in the lower stories makes it imperative to concentrate the supports there, and the failure of a single first-story column would generally involve the destruction of any of our large steel-frame buildings. Unfortunately, the first-story supports are more unfavorably placed, in regard to danger from corrosion, than any other part of the structure, for the water that is absorbed by the upper portion of the walls in storms slowly sinks by gravitation to the bottom, keeping the lower part damp, even when the upper part is dry. Some years ago, Mr. Post, we think, uncovered a wrought-iron first-story column, in making some alteration, and found it so corroded that he called the attention of other architects to it. The insurance companies also observed the circumstances, and, in consequence, as was reported, of their rather hasty deductions from them, first-story uprights, and even the wall columns of upper stories, were, for some time afterwards, very commonly made of cast-iron, on the ground that cast-iron verticals were less likely to suffer from corrosion. Architects, who often see cast-iron columns very badly corroded at the base from dampness, do not place much faith in the common superstition, and the difficulty, if not the danger, of connecting cast columns with the other members of a steel frame, led to the abandonment of this mixed construction, which is now rarely used. The question is now, therefore, practically reduced to that of the endurance of steel columns surrounded by masonry, not in the best manner, but in the manner commonly employed. Nothing can determine this question but actual investigation, and the sooner such an investigation is made the better. A twenty-story building which is likely, in the opinion of the best authorities, to fall at any moment will hardly be found a profitable investment, and the collapse of a single steel-framed office-building from corrosion would assuredly take many millions of dollars from the pockets of the owners of other buildings of the kind all over the country. In order to prevent the panic among the owners and tenants of such buildings which would certainly follow the failure of the first one, the only effectual resource is to make examinations at once, before the first failure occurs, beginning with the oldest buildings. It would be a comparatively easy matter to uncover, one at a time, the first-story columns of such a building, and replace them, if necessary, with others, better designed. This could be done, now, without exciting the apprehension of tenants, while a year or two hence it would be much more alarming, and, after one building had fallen, it would be the signal for the precipitate abandonment of every building in which it was attempted, however slight might be the real cause for uneasiness. So far as the profession is concerned, while it is the cheap structures, built on speculation, rather than those designed and supervised by architects, which have most to fear, even the latter wish to know, more definitely than is now possible, what are the conditions on which the durability of the modern mixed construction of iron and masonry depends, so that they can provide more intelligently for their future buildings, and, if necessary, direct precautionary operations in connection with existing ones. It is safe to say that no architect would willingly give up the advantages which the mixed construction offers, and it is very much for the interest of the community to use every possible means of learning how to make it secure and permanent.

THE great transportation strike in Boston came to a sudden and inglorious end, mainly through the intervention of one sensible man — Governor Crane. Instead of appealing to philanthropists or politicians, as much interested as themselves in posing before the public, the managers of the strike made the mistake of carrying their woes to a man who acts, instead of talking. When the various parties, after much newspaper interviewing and telegraphing to distinguished persons, had assembled before the Governor, the latter, instead of making an oration on the dignity of labor, and his anxiety to promote the interests of the workingmen, without neglecting those of capitalists, asked what the strike was about. This somewhat obvious question threw the strike managers into great perplexity. Nobody dared to say that it was an attempt to shut out from transportation goods not made by members of unions, or to drive out of business people who carried such goods. Fortunately, one of the champions of labor bethought himself of an old decision of the Massachusetts Supreme Court, which held that an employé of a railroad, who got on the wagon of

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

an express or transportation company, did so at his own risk; and, mentioning this decision, complained that one of the Massachusetts railway companies required its freight handlers to get on express wagons when necessary, to help the teamsters unload. The Governor listened patiently, and replied that if the unions would immediately declare the strike off, so that all the men could go back to work the next morning, he would see what he could do with the railroad company mentioned. The assemblage then retired, and the strike was forthwith called off, nearly all the men presenting themselves for employment the next morning. Meanwhile, the Governor, faithful to his promise, requested the New Haven Railroad officials to change their rule about obliging their men to get on wagons; and, although the request was declined, the main purpose, of puncturing a huge bubble of misunderstanding and pretence, and setting several thousand men at work again to support their families, at the same time that a small tangible grievance, affecting a few men, was discovered and put in the way of correction, was happily accomplished.

THE New York *Evening Post* mentions a case in which a four-story building on Broadway is being torn down, to be replaced by a two-story structure. The explanation of this is that on each side of the lot in question is a lofty office-building, with windows overlooking it. If the four-story structure should be replaced by one of twenty stories, a large number of windows in the adjoining offices would be blocked up, and the owners of the latter, in order to protect themselves, have been obliged to buy the estate; and, in order to obtain some income from it, without interfering with their own offices, have arranged for the new two-story building, which is already leased for forty years to a bank, which will occupy the whole of it. The owners of many of the New York "sky-scrapers" have been obliged, in the same way, to buy neighboring estates, often at very high prices, and will, undoubtedly, improve them in some similar fashion, so that, as the *Evening Post* says, the business part of New York bids fair to become a compound of very high buildings alternating with very low ones. In some ways, a two-story building is very attractive to a bank or trust company, and, in Boston, a firm of private bankers has already built such a structure for its own use; but the rent of a two-story building, on land costing from one to two hundred dollars per square foot, must either be large, or the owners must content themselves with a small income from their investment.

THE friends of the fine-arts in Boston will greatly regret the retirement of General Charles G. Loring from his post as Director of the Museum of Fine-Arts. Although not always under the same title, General Loring has been, practically, the chief administrative officer of the Museum of Fine-Arts since its organization, in 1870, and has seen the institution grow from a small affair to one of great importance, possessing, in certain departments, some of the finest collections in existence. In all its transactions, General Loring has been the judicious and discerning executive officer, and the favor with which the Museum is universally regarded is, no doubt, due, in great part, to his personal character. His health is, however, feeble, and a man of seventy-three, who has given thirty-two years of unwearied labor to the interests of such an institution deserves the rest which he asks for, and in which he may, it is to be hoped, continue for many years to enjoy the reward of his efforts in the knowledge of the benefits which they have conferred upon his fellow-citizens.

WE have received a letter from a correspondent in Philadelphia, warmly advocating the use of sprinklers in hotels, as a protection against fire, and mentioning that, according to the writer's information, only two architects in Philadelphia know what sprinklers are. We are quite sure that there must be some mistake about the latter point, for Philadelphia is a manufacturing city, and in all the other manufacturing towns that we know of, the architects are generally well informed in regard to the uses of automatic sprinklers, as well as in regard to the inconveniences which sometimes attend their installation. Among these, not the least is a tendency, with some sprinklers, to leak and drip, while, with others, a current of very innocent hot air, from a gas-burner or fireplace, has been known to melt the fusible alloy by which the valve is kept closed, and allow a deluge of water to escape; so that even such good things as sprinklers need to be used with discretion. Of course, there are several varieties of dry sprinklers, which, even if they open, do not scatter any water until a main valve is turned; but architects are not kept so well informed by the manufacturers in regard to improvements of this sort as would be desirable, and they must be guided by the best knowledge that they possess in deciding whether to require them in their buildings, and how and where to install them.

IT is hardly necessary to say that a hotel proprietor, for example, would view with extreme disapprobation an installation of sprinklers over the costly furniture in his public rooms, and there are not many private houses, even, where a network of iron pipes, dotted with sprinkler-heads, would be tolerated under the drawing-room ceiling. At the same time, there are many places, both in hotels and private houses, where a few sprinklers would not be objectionable, and might be of great value; as, for instance, in the basement rooms, where most of the fires in such buildings originate, and, possibly, over elevator-shafts, although it is doubtful whether a shower of water would do much to check flames entering the shaft from below, and drawn up over the oily ropes. If we are not mistaken, insurance-companies make no allowance in premium rates for sprinklers unless the building is thoroughly equipped with them; so that owners of hotels and dwelling-houses do not have this inducement to use them; but the feeling of safety which they give is worth a good deal, both to proprietors of hotels and fathers of families, and, if suitable efforts were made by the manufacturers of them to bring them to the attention of architects and house-owners, it is quite probable that the use of such an efficient and inexpensive means of protection from fire might be greatly extended.

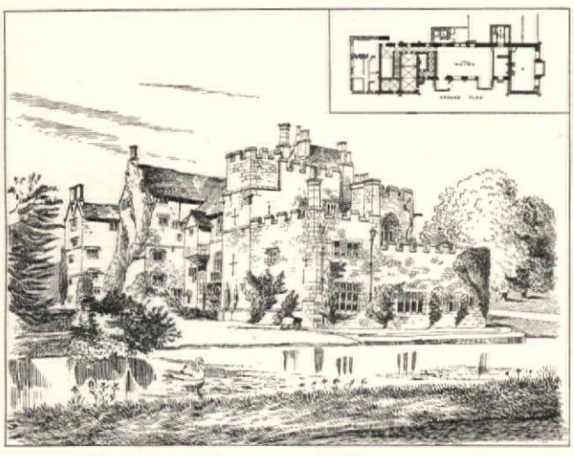
WE never like to see anybody persecuted, and it is, therefore, with a critical eye that we have followed the proceedings intended to remove Messrs. Horgan & Slattery from any portion of their employment as architects of municipal buildings in New York. Whether they are great artists or not has nothing to do with the question. If, such as they are, they were legally employed, by officials authorized to engage them, to do professional work for the city, we should not countenance any movement to take advantage of a change in the political control of the city to transfer their work to some one else, however superior the other person might be in artistic capacity. Of course, we are glad to see municipal work entrusted to the best artists that can be found, but the way to get municipal work done by great artists is to elect officials who will employ them, and not to do a wrong to innocent people who have been employed by the authorities duly chosen. It is fair to the profession in New York, and to the Corporation Counsel, Mr. Rives, to say that this has been the attitude of both, and that the newspaper clamor for the dismissal of Messrs. Horgan & Slattery has not been supported by any of the better class of architects.

THE Corporation Counsel has declared from the first that contracts legally entered into between Messrs. Horgan & Slattery and the municipal officials should be maintained. Two important ones have, however, been found plainly illegal and void. One of these, which provided for repairs on the County Court House, to the value of about two million dollars, and, in various ways, promised the architects a commission of about ten per cent on that amount, was found never to have been certified as the law requires, and, even without that, to have been plainly illegal, from the fact that no appropriation had been made for such repairs, a circumstance which, under the law, makes void any contracts entered into in connection with them. Another municipal commission has been taken away from the same architects on a different ground. They were formally instructed to prepare designs for a certain building, to cost not more than four hundred and fifty thousand dollars. The designs were made, and estimates invited, and the lowest bid was six hundred and sixty-six thousand dollars. This seemed to the Corporation Counsel sufficient reason for cancelling the commission, and there is no doubt that he was legally justified in doing so. It has been held that if the lowest bid received for a building is not more than ten per cent higher than the limit to which the architect was instructed to conform, the architect cannot be discharged for that reason, but must be allowed an opportunity to revise his plans and specifications, so as to bring the cost within the sum specified; but an excess of nearly fifty per cent would, undoubtedly, be regarded by any court as a failure, on the part of the architect, to comply with the terms of his engagement, so gross as to release the other party.

DOMESTIC ARCHITECTURE IN ENGLAND DURING THE MIDDLE AGES.[1]—VI.

PERPENDICULAR PERIOD.

THIS period of architecture, commonly called the "Third Pointed," or "Perpendicular," extended through the reigns of Henry V, Henry VI, Edward IV, Edward V and Richard III — from 1391 to 1485. This is sometimes bracketed with the Tudor period, but,



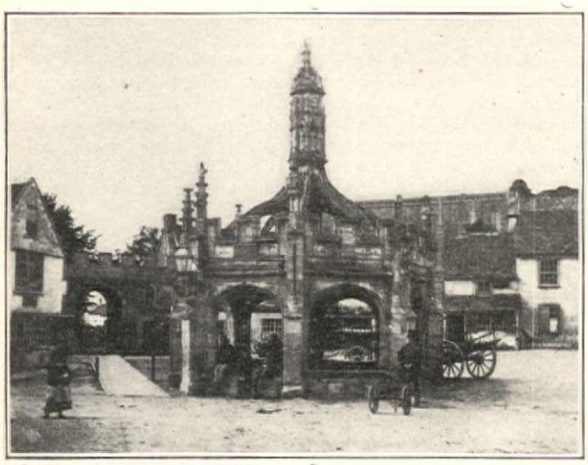
Broughton Castle, Oxfordshire.

as the latter is so well defined, and its salient features so very characteristic, it is proposed to treat it separately.

The early portion of this century was marked by constant warfare with the Welsh on the western borders, or with the Scotch on the north, with whom the disaffected barons sided more or less. There was also intermittent war with France, — sometimes truce, but never peace. It was during these wars that the ill-fated Joan of Arc formed one of the prominent features in the history of the times. During the latter portion of the period the civil "Wars of the Roses," between the houses of York and Lancaster, devastated the north of England.

Their effects on the architecture of the period were indirect, but are very apparent to the student. It was the way of the time that "to the victors belonged the spoils"; thus, a castle seized by the Royal forces from a baron aiding the King's enemies was forfeited and, by process of attainder, the owner was outlawed and all his property and estates were forfeited to the Crown. Success in war, therefore, placed great estates, money and titles at the disposal of the Crown, and these were distributed as rewards to the King's most efficient supporters. Thus, many of the castles of turbulent barons were dismantled and partially destroyed; many estates changed hands by gift or by sale, and the new proprietors rebuilt or enlarged them in the style of the period. This stimulated building and induced a certain emulation among the owners, thus incidentally advancing the progress of architecture.

The great Earl of Warwick, called the "King-maker" whose doings are so graphically chronicled by Bulwer Lytton in "*The Last of*



The Market-Cross, Malmesbury, Eng.

the Barons," was of this period. In his various mansions 30,000 people are said to have fared daily, giving some idea of the extent of the retinue of a great lord of the time, the amount of domestic accommodation he needed and his consequence in the State.

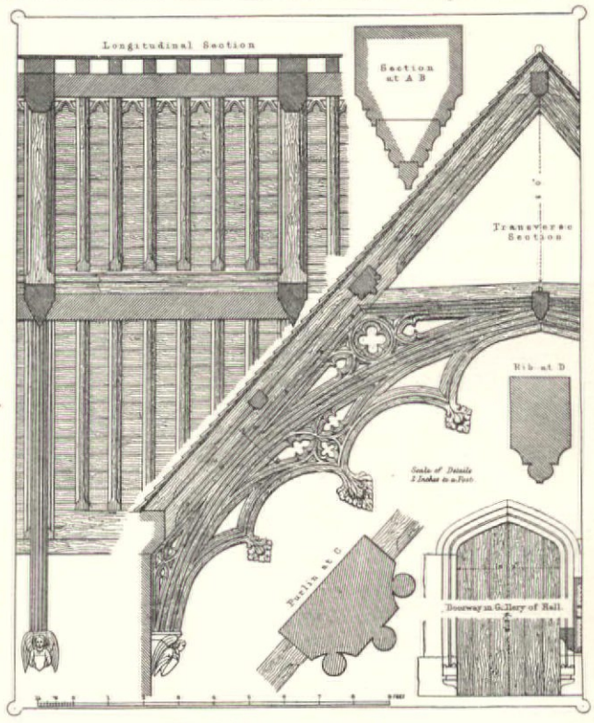
It was an age of sudden rebellious risings, sudden victories and defeats, followed by swift retribution, the attainder and beheading of the insurgent leaders, and of frequent retaliatory murders.

[1] Continued from No. 1364, page 53.

Troublous as was the fifteenth century, it was an age of increasing interest in literature and art. Princes and nobles began to take pride in the collection of books and in the encouragement of authors, transcribers and illuminators. Many of the missals, breviaries and books of these days remain as some of the choicest productions of any age, and may be seen in the British Museum and other libraries. But, as long as books could only be multiplied in manuscript, they were necessarily both scarce and costly. The monks were the first transcribers as well as authors, but, later, copying became an established vocation.

Paper at this time began to take the place of the parchment hitherto in use, and William Caxton, who had learned the art of printing from movable type in Belgium, came over and set up a printing-press in Westminster and commenced by cutting his own type in imitation of the writing of the period. The ballads of Chevy Chase and Robin Hood are of these times and are of great historic interest.

This century is also remarkable for the introduction of the mariner's compass, the discovery of India and America, and the great commercial expansion that followed. It was a time of transition in all the affairs of life and the habits and customs of the nation. Social conditions were steadily improving, and this was particularly noticeable in the dwellings of the more peaceful classes. The increase in wealth, due to commercial activity, led to a demand for greater comfort, greater accommodation, and improvement in the conveniences of living. The traders and artisans were rapidly becoming of greater usefulness to the community and of more consequence to the State. The serfs had become independent laborers, and the retainers, those that remained, discharged the domestic



The Roof: Canynges House, Bristol.

duties of the establishments. The men-at-arms that used to crowd the halls of the barons of earlier days became gradually scattered among the villages as "cottiers," peasantry and yeomen, or small traders and mechanics. These cottiers held half an acre of land or more, and paid rent in kind, the usage varying in different manors: the village carpenter repairing woodwork, the blacksmith repairing armor, etc.; others, less skilled, worked one day a week for their lord all the year round, nutting at one period, harvesting, gathering rushes, supplying fowls, eggs, honey, tending the hounds, etc., but paying no other rent. Others again, holding a small acreage of farm-land, ploughed for their lord one or more days in the week,— finding the oxen,— hauling fuel and the like. These cottiers enjoyed certain rights of common and forest and many of these obligations remain in modified form to the present day.

The lowland Scots were of essentially predatory habits, and were wont to go harrying over the moors of Westmoreland and Northumberland, and the Welsh were ever threatening the western borders of Cheshire. It was necessary, therefore, for the gentlemen of these parts to make their homesteads secure against a possible raid. If a slight eminence rose above the general level, or a favorable bend occurred in the adjacent river, these features decided the location of the proposed house. But when no such suitable position presented itself, the site was usually surrounded by a broad moat, a ditch or a "haw-haw," and admission by draw-bridge was the only means of access.

Stone, as a common building-material, was difficult to obtain in these western countries, and was generally confined in its use to the foundations, the superstructure being usually framed in heavy oak (which was abundant) and the spaces between the timbers filled-in

with wattle and clay, and covered flush with plaster. In Kent, brick is still frequently used for the same purpose. Leland describes Morley Hall as quadrangular in plan, standing upon a stone basement, which rose six feet above the level of the moat, "in the waters of which grew the 'acorus calamus,' a pleasantly scented reed, which was used to strew the floors of the chambers within." The plans of these houses were usually shaped like the letter **E**, and are very characteristic of the period.

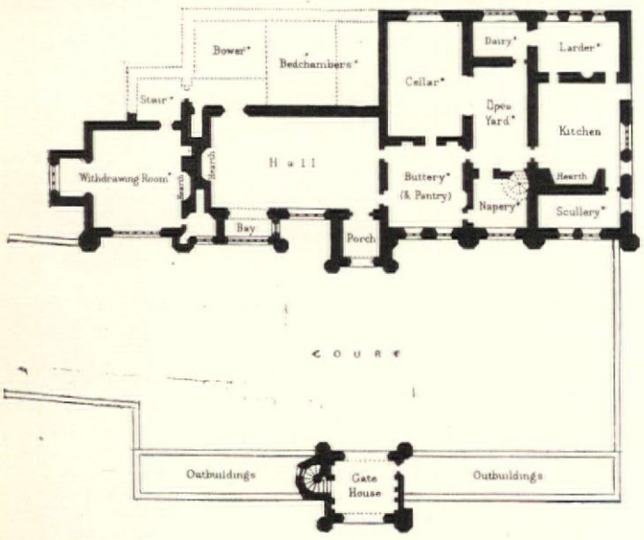
The lords of the manor frequently erected in the midst of the villages shelters called market-crosses, to which the farmer folk could bring their produce for sale or barter, the lord levying a small toll for the privilege. Leland, in his "*Itinerary*," says "these were made all of stone and curiously vaulted for poor market folkes to stand dry when rayne cometh." Chichester, Malmesbury and Northampton are well-known examples, the precursors of the market-halls of the present day.

Although the castles of the Crown, like Windsor and the Tower of London, were fortified and maintained in condition adequate to withstand the artillery of the period, the same necessity as regards private dwellings had ceased to exist, and the defensive works of many of the nobles had been destroyed. The retainers were scattered, and attention was concentrated upon the personal convenience of the owner and his family as it was understood at the period.

The "house-place," as such, is no longer found; the "common hall" remains as a leading feature with its "minstrels' gallery," but the size in all new buildings is much curtailed and the raised daïs of earlier times is usually omitted. A deeply recessed bay-window, at one side (at the daïs end) became a very conspicuous feature, and fireplaces of great size, massive construction and ornate design began to appear. The hall was no longer used as a dormitory, as of old, where guests and retainers slept off the effects of their revels, but was reserved for banquets and other great festivals.

The walls of Westminster Hall are of earlier foundation than the roof, which, with the great windows, was reconstructed at this period. This hall is 290 feet long by 68 feet wide, and the tie-beam construction (which in many smaller cases had given way to the collar-beam and arch-ties, as shown in Canynges Hall) would have seriously marred its grandeur of appearance. The consideration of its great width and the importance of the case led up to a scientific readjustment of the timbers and the development of the "hammer-beam" construction, by which the weights and thrusts were counterpoised and the resultant load securely placed at points in the outer walls, well below the level of the wall-plates. As was their wont, they beautified their salient features of construction, throwing the full height of this masterpiece of carpentry open to view, forming a feature, not only new to the world, but of surpassing grandeur and of wonderful beauty in all its detail.

The roofs over Westminster Hall, Eltham Palace (now a barn), Hampton Court and Crosby Hall, all in the neighborhood of London, are among the noblest specimens of a type of work peculiar to England. In subsequent years this great Hall of Westminster was the scene of great historic events: the trials of Queen Anne Boleyn, Sir Thomas More, the Earl of Strafford, the Earl and Countess of Somerset, King Charles I and others, who were here condemned to death and later beheaded. Here, too, Cromwell was inaugurated as Lord Protector, and the coronation banquets were held under



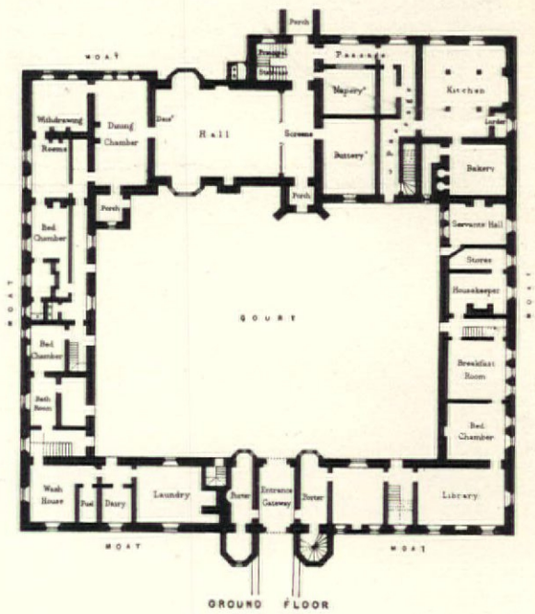
GROUND FLOOR

Wolterton Manor-house.

this great roof up to the time of George I in the early part of the eighteenth century.

Prior to the fifteenth century, flues for the conveyance of smoke from the open fires on the hearth consisted of huge canopies built of wicker plastered with clay and lime, the temporary nature of which accounts for their disappearance from the dwellings of earlier periods. In 1419, that is, during the early part of this period, we find ordinances of the city of London providing that henceforward all new chimneys shall be built of stone or brick, "and not of wood, under pain of being pulled down."

During this period we find the family chambers were grouped by themselves at the daïs end of the hall and, in like manner, that the



Oxburgh Hall, Norfolk.

offices were grouped by themselves at the other end of the hall, approached from the passage formed by the screen. Wolterton House, from Professor Ker's "*English Gentleman's House*," clearly illustrates this point.

Sleeping accommodation and the privacy of the bedchamber became much improved at this time, and the multiplication of rooms in various forms went on. Among the better class of people it became the custom to retire to special private bedchambers, assume a night-dress and sleep between sheets on feather beds. In evidence of this advance in refinement we find in the Ewelwe inventory of 1466 references made to "the great bed-chamber," "my lady's closet," "the gentlewomen's closet," the "lord's chamber," "my lord's outer closet," "washing-closet," "nursery," "wardrobe closets," etc. And we find in other records references to that cumbersome piece of furniture the four-post bed.

It is thus related that Richard III, when travelling, always took his bed with him, or had it sent on before him. In August, 1485 (as related by Hodgson), his servants had thus preceded him with the running-wardrobe and secured the best rooms at the "Blue Boar," at Market Bosworth, near Leicester, where his four-post bed was duly set up. It is described as being richly carved, gilded and decorated, and was constructed with a double bottom of boards. Richard slept here on the night previous to the Battle of Bosworth Field, whereat he was defeated and slain. This bed was subsequently stripped of its rich hangings, but the cumbersome bedstead, itself, remained at the "Blue Boar." In the reign of Queen Elizabeth, about one hundred years later, when the then hostess of the inn was one day shaking the bed she observed a piece of gold fall on the floor; this led to further careful examination and revealed the double bottom, upon lifting a portion of which the interior was found to be filled with gold pieces of the reign of Richard III and earlier. This custom of hiding treasure in beds was common in mediæval times and this circumstance is a side-light upon the habits and customs of the period.

There was a tendency among men of leisure to study and to collect manuscripts, and in the houses belonging to this class we come upon the library as a distinctive feature, as at Oxburgh Hall (from Ker's "*English Gentleman's House*"), which is another good example of the houses of the period.

The staircase now becomes a marked feature; it is still enclosed between walls, and its windows are marked externally at varying levels. Secondary, or private, stairs are also found leading from special rooms or suites of rooms, to secluded gardens, forming valuable means of escape in troublous times.

Glass, in windows, became more commonly used during this period even in the lesser class of dwellings; but it was usually fixed in moveable frames or casements that were deemed the special property of the occupier and are thus referred to in inventories and were no part of the freehold. In previous times framed blinds of cloth or canvas, or linen dipped in oil, called fenestrals, had been in use, though glass was common in the churches and monastic buildings and in the dwellings of the wealthier class.

Architecture. — The social progress is well evidenced in the plans and distribution of the dwellings of the period, but the salient features of the architecture of this fifteenth century are still more distinctive; they are as clearly defined as the Norman and the Early

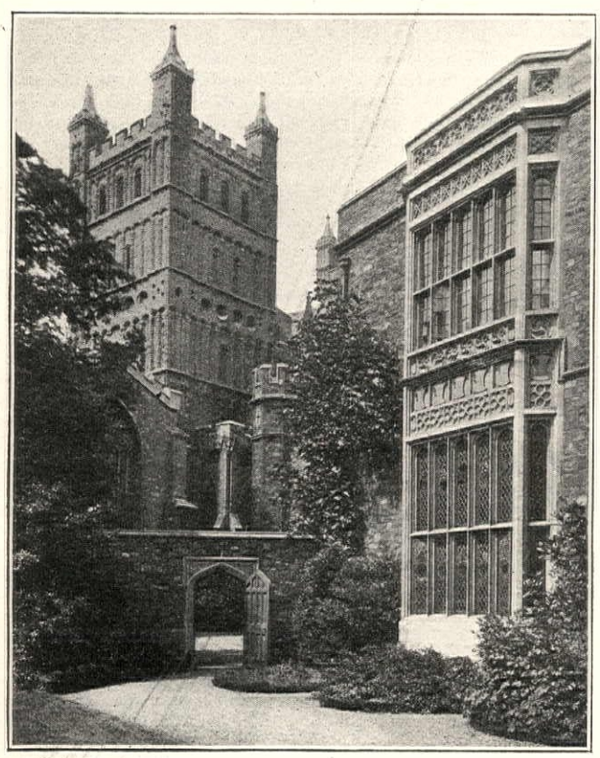
English, and form the grand culmination of the style of architecture of the Middle Ages in England.

The First Pointed, or Early English, represents the birth or inception of Gothic architecture, and is incidental to the thirteenth century. The fourteenth is an epoch of steady growth, gradual improvement in science and art, with a geometric precision in its main decorative features, an amplification and enrichment of clearly-defined ideas. But the *Perpendicular* period of the fifteenth century, while proceeding still on the same lines in the march of progress, evolves out of the tendencies of the age a most striking line of departure. It is known as Perpendicular by common consent, but *Rectilinear* would be a more apt description, as horizontality is as strongly marked as verticality. The departure from flowing or curving geometric lines, and the substitution of strongly-defined rectangular lines, are the most salient features of this period.

Defensive architecture had, as a general rule, ceased to exist; that is to say, the *necessity* for towers, walled enclosures and fortified gateways had given way in the process of evolution. The intrinsic beauty of the old features was too great, too much interwoven with ancestral history and associations, to be disregarded or ruthlessly cast aside; it became, therefore, *idealized*. The *gate tower*, when used (and we find it in the baronial and college halls of the period), formed one of a series of apartments, flanked by turrets as of old, but now marked by wide hospitable doorways, broad mullioned windows and decorative parapets; the old portcullis is remembered only by sculptured reproductions in high-relief as one of the historic associations. The roof has become flat again, but not for defensive purposes; it is approached by the turret-stair, and gives an extensive view over peaceful hamlets, cultivated fields, green meadows — the pasturage of countless herds and flocks; of general smiling prosperity and peaceful security.

The *doorways* (not gateways) were often very much enriched, the deeply-moulded arch was decorated with conventional carving of roses, crowns, *fleurs-de-lis*, portcullises, grotesques, etc. The mouldings were smaller and less vigorous than in preceding periods: small shafts with moulded caps and stilted bases. The outer mouldings were run up square at the sides and over the top, enclosing spandrels in the angles, enriched with shields charged with coats-of-arms, etc. The arches generally were broader in proportion to their height, less acutely pointed, of shorter radius.

The *windows* are of very marked character during this period. In ecclesiastical buildings and in some of the more conspicuous halls, the great windows occupy the whole space between two buttresses, the whole end of a church, the full width of a bay. Not only is their width remarkable, but also their height. They are frequently divided by leading lines or mullions into two or three compartments, and further subdivided, by secondary mullions, into two or three lights

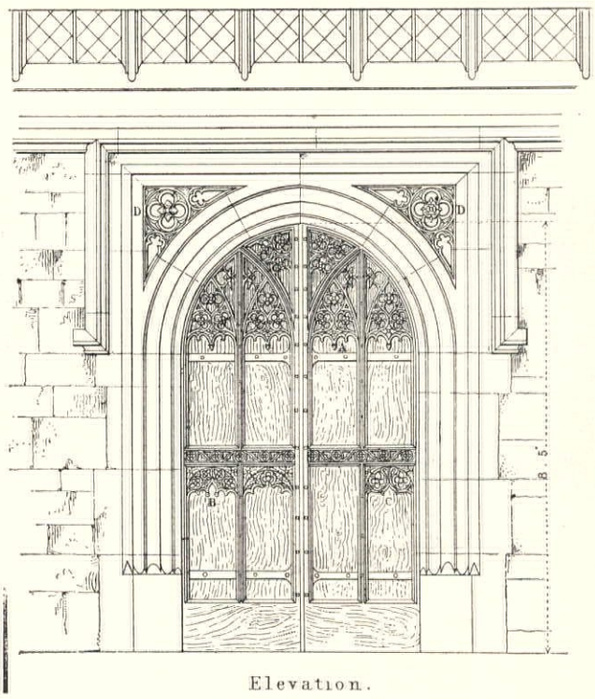


The Deanery, Exeter, Eng.

in each compartment. Not only are they divided up in their width, but in their great height by horizontal transoms, which is one of their special features. In their heads the geometric tracery of the past period is replaced by vertical mullions and horizontal transoms, richly cuspated. The windows in the great churches and halls of England of this period are the grandest and most beautiful specimens of fenestration in the world, and are peculiar to England.

The halls, as at Hampton Court, extend through two stories, and the windows, filled with the richest stained-glass, extend the full height of the hall.

Both in the *stained-glass* and in the carving of the period we find a free use of heraldry. The use of coats-of-arms has already been referred to in treating of the twelfth century. These distinguishing badges, or crests, became the heraldic device and armorial bearings



Elevation.

Doorway: St. John's Hospital, Northampton.

of a family descending, with more or less quartering, through succeeding generations. During this period we find all these salient features of warlike days idealized and the necessities of the past periods became the decorative features of the fifteenth century.

The walls were built more scientifically and with less material than heretofore, the stone facings, inside and outside, being fairly dressed. The plinths were boldly moulded and often panelled, the parapets deeply moulded, the mouldings returned round the embrasures and the face panelled. In fact, superficial panelling, both inside and outside, was one of the distinguishing features of the period, to the extent, in many of the more ambitious buildings, of covering the whole surface of the walls, inside and outside, with more or less intricate panelling, producing a very ornate appearance, as seen in Henry VII's Chapel at Westminster, at Windsor and elsewhere. This same tendency to panelling applies to doors, screens, roofs and to joiner's work generally.

Buttresses became features of great constructional importance. As the walls were built more scientifically, of stone dressed all round, but of less thickness than heretofore, and as the windows were built of greater width, sometimes to the full extent of the space between the buttresses, the whole thrust and weight of the internal construction was concentrated at these points; they, therefore, became more massive and towering; huge counterforts, in fact. They were richly decorated with panelling, niches, canopies and sculpture, as emphasizing their constructional value and importance. The canopies and turrets were mostly octagonal in plan and finished with ogee-shaped domelets, crocketted up the external angles and on the apex, in character quite distinct from anything that had preceded them which had hitherto been finished with straight lines.

In the Midland Counties many charitable foundations were established and endowed as hospitals for the aged poor, as at Leicester, Coventry, Northampton, Bristol, etc. These were built of massive oak framing filled-in flush with wattle and plaster, and many of these earlier half-timbered buildings were of beautiful design and elaborate detail. They are fully illustrated in Dollman's "*Ancient Domestic Architecture.*"

Supremely glorious are these fifteenth-century monuments, and this particular phase of the architecture of the Middle Ages is peculiar to England.

The rapidly increasing wealth of the times led to liberal patronage of the arts, and a certain emulation of display, to great building activity and to extravagance in ornamental detail. It was thus that the architecture in England during the Middle Ages, the mediæval times, rose, by adventitious circumstances, to its zenith, its greatest glory and development, and, for a century or more, it was high noon; but slowly and reluctantly, the sun of mediæval art began to decline. The days of true-art progress, the days of ever striving for fresh forms, more beautiful, more perfectly consistent than had hitherto been developed, gave place to days when the mechanical reproduction of established forms was often made grotesque by the on-grafting

of incongruous features copied from pre-mediæval times, the cumulative result of which was that distinctive style of architecture known as Tudor.

THOMAS C. SORBY.

[To be continued.]

THE BOSTON STRIKE.

"NOTHING could be more unreasonable than the demands of the workmen who have precipitated the great Boston strike. Only on the theory that a labor union's wishes take precedence to all law and that the whole country must, without interest or knowledge, instantly on the demand of a few labor leaders take up a controversy can such a proceeding as that taken in Boston be justified. No other body of men in civilized society presumes to hold up a whole nation for the settlement of petty grievances of a handful of persons. The disproportion of cause and effect is simply grotesque. The whole trouble arises out of an insignificant quarrel between organized labor and a local trucking company of Boston. What the merits of the question originally at issue were we do not attempt to determine. No matter how justly bitter the labor unions may have been against this concern, they were not in the least justified in venting their ill-will on the public at large, as they have done, causing suffering to thousands who never heard of the carting company and are perfectly helpless to influence the struggle.

"Having declared a boycott against the carting company, the strikers demanded that the railroads and steamship lines should refuse to handle any goods brought to them in this company's trucks. Such a demand, of course, could not be granted. The railroad and steamboat companies are common carriers. They are by law obliged to handle the freight that is brought to them. They may dislike the bringer and sympathize with the strikers against him; nevertheless, his right to the equal privileges of public transportation is absolute. It is a right which those who proclaim themselves the special friends of labor are always seeking to surround with additional safeguards. Transportation corporations, it is demanded, must make no discrimination between customers, they must charge the same rates to all, they must favor nobody, whatever his power or his relation to their business. But, if they must favor nobody, they must also punish nobody. If they can refuse to handle one man's goods because he is boycotted by a labor union, they can refuse to handle another's because he is competing with some friend of the railroad managers. If a railroad can do what the Boston strikers demand, a telegraph company can refuse to transmit the messages of any person on the request of his enemy who has influence with the telegraph directors. The next step is to establish the rule that the Post-office Department must close the mails to any person on petition of organized labor. Nor is it much of a step, either. Labor unions have gone much farther in other directions. They have long proclaimed the doctrine that a person under their ban was not entitled to the equal protection of the laws, and declared it outrageous that policemen or sheriffs or soldiers should guard him from violence or save his property from destruction.

"This is anarchy. The Boston strikers are acting just as much on anarchist principles as the men who throw bombs. They are demanding that persons against whom they have a grievance be outlawed and that others be freed from performing their legal obligations towards them. If common carriers may not transport a boycotted concern's goods, may the courts try their suits, may the street-cars take them as passengers, may the fire-department keep their houses from burning down, may the police protect them from assassination if a labor union sees fit to object? There is no middle ground. The lawful rights of every citizen must be respected, even if he is justly hated by organized labor, or else anarchy reigns, and when individual rights cease to be sacred it is always the poor man who suffers in the end. — *N. Y. Tribune.*"

BOOKS AND PAPERS

EIGHT years ago an undergraduate in the civil-engineering course at Ann Arbor chose for the theme of his graduation thesis "Architectural Engineering," handling the subject so well that the attention of Wiley & Sons was called thereto, with the result that in 1895 the thesis, extended and elaborated, was published under the title of "*Architectural Engineering.*" The first edition was noticed in these columns on November 16, 1895. The second edition of the work[1] is now before the public. In a way, it admirably illustrates the fact that the engineering demands upon the architect have vastly multiplied even in the six years since Mr. Freitag's first edition was published. Previous to 1894 Chicago stood first in the construction of high buildings, and the descriptions and examples cited in the first edition were mainly limited to Chicago practice. Indeed, it was customary at that time to speak of skeleton construction as the Chicago system, and the type was not looked upon with a great deal of favor by Eastern constructors, but business necessities have forced a consideration of the special problems involved in high buildings, and the East, particularly New York City, is at present far ahead of the West in the magnitude of its building operations, both up and down. That is to say, the problems of foundations are to-day more complicated in New York than elsewhere and tall buildings have been carried to a greater height in that city than was ever known before. The last six years have also witnessed great changes and improvements in many details of construction, especially in terra-cotta and concrete floors and in all methods of fireproofing. It follows therefore that the work under present consideration is a second edition in hardly more than its title-page, for so much new and different matter had to be incorporated and considered that the practical rewriting of the book was inevitable. The number of pages has been increased from 239 to 407. The illustrations are drawn from all over the country rather than from Chicago, the New York methods receiving special attention. The greatest fault we would find with the work is that the original edition was not entirely discarded and the whole volume rewritten. It would have gained immensely in clearness and preciseness. The old material crops out conspicuously in places, and the illustrations are distributed in such manner as just not always to agree with the text. But this, after all, is not especially material. The real value of the work is beyond question and it easily leads in its class. We know of no one book which can be so thoroughly commended for both the beginner and the experienced practitioner.

While the title is comprehensive the real discussion is practically limited to the tall steel-constructed office-buildings. The modern office-building presents almost, if not quite, all the problems involved in architectural-engineering. The arch has practically ceased to be a constructive member. It might almost be added that we have ceased to place any special reliance upon masonry as a supporting member, so that a modern building resolves itself practically into a foundation and a steel cage. Therefore the author is quite right in limiting his consideration to this type of building, and occupying the bulk of the volume with considerations of steelwork.

The chapter on columns is of especial interest. This is the one feature of building-construction about which we are to-day the least informed. We continue to use Gordon's formulas and the rules-of-thumb given in the Carnegie tables, and the fact that they answer most requirements is because they are really based upon the results of tests. But even in this respect our information is limited. There is an almost complete absence of definite data in regard to the ultimate strength of actual columns. Tests on short lengths of slight sections have an undoubted value, but they are not conclusive, and it is to be greatly regretted that it is not possible to institute a series of investigations which would give us data as conclusive in regard to columns as the investigations of men like Professor Lanza have been as to beams and girders. It is always a satisfaction to calculate a girder. One has a feeling of absolute confidence in the results which is quite lacking in the computation of a column. The radius of gyration is a convenient expression which covers a vast degree of ignorance, and until we can get down to a more basic scientific formula we have to be content with rules of-thumb. Mr. Freitag's discussion of column-loading, to our mind, in a degree misses the actual mark. He cites one instance of eccentric loading in which the statement is made that a cast-iron pillar 10 inches in diameter and 11.9 feet long will break under a centre-load of 32,000 pounds per inch of metal area, while if the load is placed one inch to one side the unit resistance is reduced to 21,150 pounds, and a difference of only one-half an inch off the centre-of gravity gives a reduction to 26,050 pounds. These are interesting figures, if true, but without questioning Mr. Freitag's good intent we frankly do not believe they would be substantiated by practice. In our own experience we have seen it proved repeatedly that a slight degree of eccentricity makes no appreciable difference in the strength of the column, and reasoning from practical considerations it would seem far wiser to systematize and balance our loads rather than to undertake the extremely uncertain problem of designing columns especially for eccentric loading.

The author takes up quite exhaustively a topic which we are always interested in seeing discussed and about which a great deal has been written of late years, but which is so intangible that it leaves possibilities for wide differences of opinion. We refer to the subject of wind-bracing in tall buildings. While we know that the wind does blow and blow hard, we have not, however, actual observations that will tell us to what extent a recorded wind-pressure at one point is exerted all over a side of a building, and therein lies the difficulty of rightly solving the problem. The admirable investigations made by Mr. Julius Baier on the St. Louis tornado and its effect on buildings constitute perhaps the most important addition to the literature upon the subject. All of this is carefully considered by Mr. Freitag, who very rightly, we believe, errs on the side of safety, and yet he places far more insistence upon a possible wind-strain than would seem in our judgment necessary. Applying the formula of the United States Weather Bureau, $P = 0.004\,V^2$, to the extreme velocity recorded in the St. Louis tornado, gives a pressure of 60 pounds per foot. The maximum velocity ever recorded in New York lasted only two minutes and resulted in a pressure of only $22\frac{1}{2}$ pounds per foot. And yet the engineers would tell us that we should assume not less than 30 pounds per foot, and should transmit every pound of this strain directly to the steel frame, disregarding the masonry walls, and that the resulting stresses on the structural members added to the stresses from the constructive and live loads should not be more than one-fourth of the ultimate resistance of the metal. Mr. Freitag assumes that the floor construction can be counted upon as sufficiently rigid to transmit the horizontal shears due to wind, and yet he is not willing that any reliance whatever should be placed upon the resisting factor of the masonry walls and partitions. And this notwithstanding his admission

[1] "*Architectural Engineering.*" With Especial Reference to High Building Construction. By Joseph Kendall Freitag, B. S., C. E. Second Edition. New York: John Wiley & Sons. 1901. Price, $3.50.

that most careful observations on the deflection of tall steel-skeleton-construction buildings in Chicago tend to show that any actual deflections in well designed and carefully constructed buildings, even under very heavy winds, are far less than any theoretical assumptions. No amount of argument except actual experiment will ever convince us that any plate-glass window of even moderate dimensions is capable of resisting a direct thrust all over its area of 30 pounds an inch, and though recorded velocities and even recorded pressures may give high readings at isolated points we have yet to see any facts which would show that such pressures or velocities are due to more than relatively fitful gusts which operate against only isolated portions of a building. The building-law of New York allows the working-stresses from wind-strains to be increased 50 per cent over what is permissible for other loadings. But where the metal, even under such conditions, is not loaded to anywhere near its elastic limit, we fail to appreciate any evidence that would make us hesitate to assume a wind-pressure in a tall building of not over 10 pounds a foot, and we doubt very much whether even that would actually exist. This is a subject which offers a fruitful field for discussion, while we have regarding it a dearth of real knowledge.

The chapter on spandrel sections is a very clear presentation of a feature of steel-construction which is often neglected. The facts are put in very usable form and the best practice is illustrated and explained. There is also an admirable discussion of the use of column sheets in making calculations, with a number of illustrations from typical buildings. The proper tabulation of computations, presenting the figures in such way that when the problem is an old one the process of calculation will not be forgotten, is a factor of considerable importance. We could wish that Mr. Freitag had seen fit to apply a similar process of formulation to beams and girders, which are not considered at all, though quite as important in their way as the column tabulations. In a work which covers so wide a field, however, it is natural that there should be some slips, as for instance when in the formula $p = 17{,}100 - 57\frac{l}{r}$ the value of l is said to be in feet, while r is in inches. Again, the writer makes the interesting statement that in Boston piles are used almost exclusively for foundations, which will be news to Boston architects. And on page 187 the statement is made that for openings in walls where beams or members are supported directly by the walls the load generally assumed to be carried in masonry of usual bond may be represented by a triangle whose base equals the clear span and whose height equals one-third of the span. A brick wall will, of course, bond itself over an opening, but it does not seem to us good engineering practice to depend upon such bonding, and it certainly is not so considered by many constructors. But these are, after all, minor defects of relatively slight importance and can easily be corrected in what we hope will be a subsequent edition. The work as it stands is so thorough and complete that it disarms criticism, and even taking into account the local character of the first edition, in its present form it is certainly standard.

A VERY excellent little book [1] is Mr. Leslie Waterhouse's "*Story of Architecture*," one of a series called the "*Library of Useful Stories*," perhaps rather unwisely.

"The waters of the Nile are the head-waters of architecture," says the author not inaptly; and from these head-waters spring all the great rivers and small rivulets and brooks of Greek, Roman, Mediæval, Renaissance and modern architecture — if such a thing as architecture exists in the modern sky-scraper. Certainly, if architecture arose, as it seems to have done, in the earlier centuries from the religious faiths of nations, the hideousness of modern houses may be accounted for, as there is certainly no faith shown forth in them, religious or otherwise. "Nothing reveals the character of the nation so clearly as its religion; nothing has a more permeating influence upon its architecture." And thus the Egyptians, being not only a religious people, but having a vast number of deities, planned their temples upon the grandest scale. When one thinks of the Great Pyramid occupying 13 acres, or twice the extent of the foundations of St. Peter's at Rome, some idea may be formed of the stupendous character of Egyptian buildings. Its height is 481 feet, that is, 57 feet higher than the spire of Salisbury Cathedral; and it has been said that it would occupy the entire space of Lincoln's Inn Fields, London. Such vastness is lost in the desert; but could we erect a temporary pyramid in any of our great cities, we should then gain a fair idea of the stupendous grandeur of those early builders of 3700 B. C.

Mr. Waterhouse's summing-up of the French-Gothic churches (by the way, he insists upon the folly of the term Gothic, although we must bear it for want of a better, equally comprehensive, and compares Amiens with Salisbury, both being about the same date. The height of the nave of Amiens is almost double that of Salisbury, 140 feet and 84 feet, respectively); and the height of the *flèche* is nearly that of Salisbury spire (424 feet), hence, the meanness of the interior of the English church as compared with the French one. The richest feature of French cathedrals is the deep recessed porch, so superior to the English doorways. The earliest Pointed arches in England appeared at Malmesbury and Kirkstall Abbeys. The superb beauty of Canterbury and Westminster is due, probably, to a French architect.

The peculiar character of the English chapter-houses, the circular or polygonal plan, with a central column from which ribbed groining springs was first adopted at Worcester, the earlier chapter-houses having been square or oblong, as at Bristol and Gloucester.

Mr. Waterhouse speaks of Köln as the "finest of all" Gothic churches, to which we may be allowed to demur. It is, no doubt, of French plan, but surely many of the cathedrals of France are far more impressive and beautiful. At page 164, the author cites Köln (Cologne he calls it) as the "largest of all Gothic cathedrals, with the single exception of Seville"; while at page 158 he gives Milan as "the largest of all mediæval churches, except Seville."

Considering that the little book contains but 207 pages, and gives the whole story of the growth of architectural plans, forms and details, it is not too much to say that very little, indeed nothing, of any importance to the young person or the full-grown amateur is omitted. It is just the sort of book one wants as a text-book for the young, and a concise and instructive handbook for others. There is not too much of a technical nature, but architectural terms are not omitted; and any one mastering its contents need not fear being superficial, even if he goes no farther; but the book would form an excellent foundation upon which to build a more elaborate knowledge of architecture culled from Fergusson, Parker, Statham and others. Of course, it is not intended for professional architects.

NOTES AND CLIPPINGS

THE DIMINUTION OF THE RED-CEDAR SUPPLY. — Reports from Puget Sound show that the supply of red cedar suitable for shingles is becoming smaller every year and that the manufacturers will soon have to go to Alaska for cedar logs. New appliances have so greatly increased the output of mills that last year 5,000,000,000 shingles were cut in Washington and Oregon. Good cedar logs command $9 a thousand feet, and the supply is short at this price. — *N. Y. Evening Post.*

English Borough of Bermondsey lighted by Garbage.—There was a large gathering at Bermondsey Town-hall, according to the *London Times*, when the borough opened the new electric-lighting and dust-destructor works which have lately been brought to completion by the Bermondsey Borough Council. The new works are situated in Spa Road, at the rear of the Town-hall and public baths, and they occupy an area of about 1½ acres. The buildings consist of a destructor-house, an engine-room containing the generating plant, a pump and fan room, an accumulator-room and offices. The destructor-house is specially designed with the view of giving adequate ventilation. It consists of six cells, each having 26 square feet grate-area, and capable of destroying fifty tons of refuse in twenty-four hours. The refuse to be destroyed is brought in by the collecting-vans, conveyed along an inclined roadway to a tipping floor at the back of the destructors, and discharged into spacious bins placed over the tops of the cells, from which the latter are fed as required through rectangular shoots. After passing through the shoots the refuse is deposited on a hearth at the back of the furnace, and is there thoroughly dried before the actual burning takes place. By these means the refuse is rendered more combustible and the vapors which are given off become innocuous by being passed over the hottest part of the furnace. The gases from the cells pass out at the front and come into contact with the boiler-tubes, and are thus utilized for the purpose of raising steam. Each cell and boiler furnace is fitted with forced-draught apparatus. In deciding the system of distribution most applicable to Bermondsey, the engineers had under consideration the fact that the district is very concentrated and is filled with factories and workshops, and that the most favorable opportunity occurred for supplying electricity during the daytime for motive-power purposes. The alternate-current system was therefore not deemed so suitable as the continuous-current, which has been adopted. The plant at present installed in the generating-station consists of three multipolar generators. Two sets each have an output of 150 kilowatts at 480 to 520 volts, and the third set an output of 75 kilowatts at 480 to 520 volts. There are also installed in the station a balancer and a battery-charging motor booster. The battery, which consists of 280 cells, is capable of giving a discharge of 83 ampères at 510 volts for six hours, or on an emergency 300 ampères for one hour. The switchboard is an interesting construction, and is mounted in a wrought-iron frame. It consists of panels of polished black enamelled slate. The board has been designed to control three dynamos, six feeder-circuits, eight arc-circuits, the Town-hall, the depot and station lighting-and-power circuits, the storage-battery, the balancer, and the battery-charging motor booster. In the borough the three-wire system of mains has been adopted, and the feeder-mains are at present four in number. With regard to the public lighting, there are at present 71 standards erected, supporting ten-ampère double-carbon arc-lamps and incandescent-lamps. At twelve o'clock every night the arc-lamps are permanently turned out and the incandescent-lamps are lighted. The new stables, when completed, will afford accommodation for sixty horses. At present only fifty-four stalls are fitted up. The new depot also includes workshops, stores, offices and other buildings for municipal purposes. Mr. T. Cox, Chairman of the Electric-lighting Committee, who presided, stated that the charge for electric-lighting would be twelve cents for the first hour and six cents for each hour afterwards, based on the minimum-demand system. For motive-power purposes the charge would be five cents per unit. He remarked that the question of the disposal of the residuum from the destructor had occupied the attention of the Council, and an electrically driven hydraulic plant for the manufacture of flags from a portion of the clinker had been laid down. That machine would turn out flags at the rate of twenty-five per hour at a very low cost. The clinker was ground very fine, mixed with a due proportion of cement, thoroughly incorporated, and then subjected to a pressure of 1,000 pounds per square inch and afterward allowed to dry.

A Pacca Law suggested for France. — The Paris *Chronique des Arts* protests against the sale of ancient French art-works to foreigners, and advocates the passing of a law similar to that now in force in Italy forbidding the export of any art-work exceeding $1,000 in value and 100 years in age. It instances the sale recently of a rare specimen of old wrought-iron, a screen of eighteenth-century work that stood in the choir of the Trèves Cathedral, which came originally from the church at Clairvaux. The cathedral authorities, needing money for a new heating-apparatus, put it up at auction. The town, wishing to save it, carried the bidding to $2,800, when a rich American, name not given, bid $2,900 and got it. It is also said that many French châteaux and churches have been robbed of carved wood, stone and iron work by foreigners, and the *Chronique* foresees the day when America's superiority over the Old World in the possession of money will lead to wholesale despoliation, unless a stringent law is passed against such sales.

What is a Block? — In the talk of New York the word seems most commonly to denote a distance — the stretch of one street lying between two intersecting streets, or, north and south, in the numbered streets, the twentieth of a mile. When the phrase has any other meaning, real-estate men, at all events, feel constrained to qualify it by the boundaries of the property. Here the distinction has slight importance, but in Chicago the precise meaning to be attached to the word has lately been the decisive factor in determining the efficacy of the local-option laws, which certain districts of that city enjoy. According to the law, a saloon or dram-shop may not be established in any block without the consent of the majority of the property-owners in that block. The liquor-dealers naturally chose to interpret the word as an expression of distance, and when they had obtained the consent of a majority of the property-owners on either side of that portion of the street between two intersecting streets on which they proposed to open up, they professed to have done all that the law required. The different municipal authorities, with the coöperation of sundry municipal associations, opposed this interpretation in the courts, setting up the contention that a block was a tract of land bounded by four streets, and that in order to comply with the law, the liquor dealers would have to obtain the consent of a majority of property-owners upon each side of the streets which bounded the block. In the lower courts the saloon-keepers won, but, on appeal, the Supreme Court of the State of Illinois has lately decided that the contention of the city and of the protective associations is correct, adding that a dram-shop affects the value and character of all the property in the block in which it is situated, and that "to hold under the ordinance in question that the consent required was only from the property-owners on each side of the street in which the dram shop is kept, instead of each side of the streets surrounding the block, would manifestly lead to absurd results." Under the terms of this decision, a number of beer-gardens in the residence district will be obliged to close up, and as the ordinance was widely copied by smaller municipalities throughout the State, the final interpretation of the phrase is likely to have far-reaching results. — *N. Y. Evening Post.*

A Draughtsman's Ring. — An Englishman has invented a writer's or artist's ring. The ring carries a small steel ball, so placed as to revolve freely in any direction. With the ring on one's little finger, so that the ball is at the point of contact with the paper, almost every bit of friction in the movement of the hand upon the writing or drawing material is removed. — *Exchange.*

Niches. — The abundant use of statues by the Romans led to the adoption of the niche — a feature unknown in Greek architecture — as a convenient mode of inserting them within the surface of walls and thereby decorating them; at the same time space was gained in interiors where, if otherwise placed, they would have taken up room. Niches frequently occur in Roman temples and baths, and were occasionally decorated with a frontispiece of small columns, with their entablatures and pediments, but were generally left plain, and were for the most part semicircular in plan, in which case they usually terminated in an arch and semi-dome, after the manner of a tribune, or large recess, of which the niche was, in fact, a miniature copy. Niches, however, were very frequently rectangular in plan, and were also *exedræ*, or recesses, in which case the latter formed arches vaulted hemicylindrically. — *Stone Trades Journal.*

Some eccentric Railways. — As the iron track is bound to force its way into most corners of the world, it is not surprising that some lines of railway exist which are striking evidence of a singularly bold conception carried out in the face of obstacles which seemed almost insurmountable. Sometimes the route of the future line lies across a desert; then the great law of the "compensation of nature" seems to make itself felt, for to balance the saving of time and money due to the fact that long tunnels will not have to be cut through hills or mountains the engineers are confronted by the total absence of three essential elements of construction, namely, wood, iron, and water, which have to be transported along the newly-laid line as it stretches its slow length across the desert. Russia's Trans-Caspian Railway, now know as the Central Asian Railway, was built under these conditions; thousands of logs of timber were needed, and the region traversed cannot boast of a single tree for more than 700 miles. This timber was required for building the long bridge, two miles in length, over the River Amu-Darya. This bridge was always the weak point in the highly important railway, and it has been replaced recently by a stone bridge. Between Merv and Charjui the line had to be carried over shifting sands 64 feet deep. When the work is being carried out in such regions the trains become a little town on wheels. They are composed of two-storied wagons, which contain sleeping accommodation, butchers' stalls, canteens, grocers' stores, and forges. As the Trans-Siberian Railway grew in length it was resolved by the authorities that the workmen should have their own "church car." A wagon was fitted up accordingly as a church, with a little peal of bells in the alcove above the entrance. The romance of mountain railways by no means ends with their construction, and travelling upon railways at a very high altitude is not a thing to be desired. The Peruvian line running from Callao to Oroya has a twofold claim to distinction; it is built at probably the greatest altitude of any existing railway, namely, 15,906 feet above sea-level, and it affords travellers certainly the most unpleasant "expérience de voyage" that can be imagined. As the result of travelling at such an altitude, the passengers begin by feeling great oppression, accompanied by pains in the head and limbs; these are quickly followed by bleeding from the nose and mouth, and then by momentary blindness. It is gratifying to know that there is a certain variety in the effects produced upon passengers at this point. Thus, while some persons are seized with giddiness, others entertain strange hallucinations, and others faint away; the last class become so weak that any undue exertion on their part often proves fatal. But this is not all that one has to undergo on the Callao and Oroya line. In due course the skin becomes irritable and sores break out, while the lips swell and then crack. On one of the Trans-Andes railways the passengers have to enter the train in a most peculiar and probably unique manner. The line referred to is that in the port of Mollendo, in Peru. The line starts from the quay-side, and the traveller can pass from the boat into the train. Unfortunately the boat cannot be brought completely alongside the quay. Disdaining the usual gangway, Peruvian ingenuity hit upon a very novel idea. Two large uprights, with a strong cross-bar, were erected on the quay, and from the cross-bar hangs an ordinary trapeze. The passenger wishing to land has to seize the bar of this trapeze; a few sailors surround him, and, when he gives the word, they unite in hurling him into space over the ship's side. One such "send-off" is quite enough, for with one swing the traveller comes to land in the outstretched arms of the railway porters. It is only right to add that both the sailors and the porters evince an amount of energy, delight, and dexterity quite equal to the nervousness of their victims. — *London Globe.*

NOTES AND CLIPPINGS. 104

WE will call to the attention of subscribers to our International Edition that the current issue is, for the present at least, the last one that will be sent out in the familiar form it has borne for so many years. We shrink when we picture to ourselves the number of times that during the coming weeks we must give special explanation to subscribers who have happened not to observe our repeated warnings and so find themselves obliged to demand an explanation of the apparent substitution of the copies of the Regular Edition for the International Edition to which they have subscribed.

MR. EDWARD ATKINSON corrects our account of the fire in the Park Avenue Hotel, in New York, and sends us a copy of the extremely interesting report of it which he made after personal examination and inquiry. It seems that the heat from the burning armory, one hundred and ten feet away, did not even crack a single window on the side of the hotel exposed to it. Two men in the hotel opened a window, and sparks from the armory blew in, and set fire to the curtains; but the window was closed again, and the blazing curtains extinguished, without any communication of the fire to other rooms; and it seems most probable that the fire in the hotel was simply simultaneous with that in the armory. Possibly a spark from the armory may have floated into the elevator-shaft, but a dry bearing in the elevator-machine at the foot of the shaft, or a short-circuited electric-wire, would fully account for all the phenomena. However it may have been kindled, it is certain that the fire began in a brick elevator-shaft, at the bottom of which was an hydraulic motor. The motor chamber was sheathed with wood, but the walls of the shaft above the basement showed only the bare brickwork. There were, however, windows in the shaft, on every floor but two, looking into the courtyard, and a wooden platform spanned the shaft at every window, to facilitate washing the glass. On the side toward the hall there were the usual wooden elevator-doors, with glass in the upper panels. The platforms in the shaft were more or less burned, the upper ones more than the lower, showing that the fire gathered intensity as it ascended. There seems to have been no skylight at the top of the shaft, to draw the flames inward and upward, and the wooden platforms acted as deflectors, throwing the fire against the windows in the shaft, and the panes of glass in the elevator-doors, all of which were broken. It is a most significant circumstance that, except the breaking of these windows, and the burning of the platforms, hardly any injury was done to the building, the sad loss of life having been due almost wholly to the smoke. The fire grew more intense as it proceeded upward, and the highest flight of stairs, which was principally of wood, and was very near the shaft, was destroyed. The other stairs, which were of iron, were uninjured, and not a single door from the hall to the rooms was burned through; yet the smoke which came into the rooms through the crevices, and, in some cases, through the open transoms, was sufficiently dense to suffocate their inmates, and, in the hall itself, it was, of course, impossible to live. As the building is constructed almost entirely of iron and masonry, with brick partitions and floor-arches, the smoke which proved fatal to so many persons came mainly from the burning of the carpets and furniture, and the flames from the elevator-shaft, which was practically a blast-furnace, one hundred and thirty feet high, were so intensified as to burn very rapidly whatever they could reach. In this way a book-case, filled with books, standing in the corridor of the upper story, was so completely and quickly destroyed that not a trace was left, even of the books; and in the story below, the furrings and laths on the walls, which were furred and plastered on wooden laths, in the old-fashioned manner, were consumed, down to the brickwork. In the other stories, the fire seems to have fed mostly on the varnish of the woodwork, and the carpets, with their cotton linings. The resistance of the painted wooden doors of the rooms, even in the upper stories, to heat so concentrated is remarkable, but they were all set on the room side of the thick brick partition wall, and, consequently, were deeply recessed, and this is not the first time that it has been observed that a quantity of air, imprisoned, so to speak, in a recess, and thus prevented from circulating, is a very effective shield against fire. If the doors had been covered with metal, and the transoms glazed with wire-glass, the occupants of the rooms might, with full confidence, have closed the transoms, and put their heads out of the windows, to get fresh air to breathe until the fire in the hall should be extinguished; but it is not wonderful that with nothing but unprotected wood and thin glass between them and the flames which they could see through the transoms, some of the guests should have lost their presence of mind. The moral of the whole sad story, like that of so many similar ones, is that, however fireproof a building may be, the people in it may at any time be suffocated by smoke from burning curtains, carpets, furniture or varnished woodwork; and that these must be eliminated so far as possible from halls and open places in hotels, or, at least, protected by sprinklers.

A LETTER to the Boston *Transcript* on methods of building for protection against fire, while excellent in intention, contains so many mistakes and misapprehensions as to deprive it of much of the influence that it ought to have. The writer after saying that the Park Avenue Hotel in New York was "totally destroyed," because it was "not properly constructed, every air-space being open for the spread of fire and smoke from the cellar to the roof, and no protection whatever to the elevators," goes on to argue that buildings should be "divided and subdivided," to "prevent the instant spread of flames and smoke, now possible throughout the entire structure," and that fireproof shutters should be applied to outside windows. In confirmation of the value of these precautions, the writer quotes the example of Paris, where the compartment system has been in use, he tells us, "for many years."

AS a matter of fact, the Park Avenue Hotel, which the writer holds up as a warning, was perhaps the most perfect example in this country of the application of the compartment system. Not only were all the floors of iron and brick, but nearly all the partitions between the rooms and halls, and between the rooms themselves, consisted of brick walls, and the elevators and two of the stairways were enclosed in brick walls, and the consequence of this solidity of construction was that the fire which caused the death of several people in it, instead of "totally destroying" the building, did very little injury to it. Mr. Edward Atkinson's report of the fire says that "no exterior damage was done," not a single pane of glass on the street-fronts was even cracked, the stairways were uninjured, except the topmost flight of one of them, and the fire, if we understand the report, did not make its way into any of the rooms, being confined entirely to the main hall; and the deplorable loss of life was due entirely to the smoke, which filled the hall and stairways so that they could not be used, and

Entered at the Post-Office at Boston as second-class matter

penetrated into the rooms, through the crevices around the doors and transoms, in such volumes as to suffocate people who were as safe from actual burning as if they had been a mile away. The *Transcript* correspondent, like so many other newspaper writers, is also in error in speaking of the "compartment system" of building as being particularly well understood and practised in Paris. While dwellings in Paris are usually divided by partitions of masonry, and floors are filled-in with plaster rubbish, the great stores there are striking examples of the lack of the precautions which our architects and fire-engineers consider necessary. In similar stores in London real subdivision is practised, and the shopper at any of the great department-stores on Regent Street or Oxford Street is sent through an endless succession of narrow doors in heavy brick walls, or through tunnels under the streets, to find what he wants. Most Americans, comparing the insignificant appearance of these strings of little rooms with the splendors of Siegel & Cooper's, or Macy's or Wanamaker's stores, imagine that the English are too penurious to pull down a whole row of old houses to build in their place an imposing establishment, and, therefore, content themselves with cutting little holes between the old buildings, and utilizing them without further alteration; but, whatever may be the origin of the English system, it offers great security. In Paris, on the contrary, vast spaces, open to the roof, and filled with combustible goods hung, piled and spread wherever there is a place for them, are as common as they are in New York, while automatic-sprinklers and similar appliances used in such places in this country are practically unknown. The French are habitually careful, and it is through this circumstance, much more than on account of their superior skill in construction, that great conflagrations are rare, not only in Paris, but on the Continent generally. It is probable that the habit of caution in regard to fire, which is carried so far that, in the forests belonging to the city of Heidelberg, it is forbidden even to throw a bit of paper on the ground, and much more to light a match, originates in neighborhood liability of every house-owner or tenant for damage from fire spreading from his premises to others, which is almost universal on the Continent. A man who has to pay for the actions of a fire originating on his premises, exactly as if it were a pet dog which he allowed to get out and bite his neighbors, finds it for his interest to keep his fires and his vicious dogs within bounds; and, insensibly, the habitual construction in France, Italy, Spain, Austria and Germany has become one adapted to confining fire to the room in which it originates. In the simple precautions by which this end is attained the Continental builders of dwelling-houses have become more and more expert, and, as it seems to us, a similar system would, in time, lead to the same result here.

THE operations on the New York Rapid Transit tunnel have been unfortunate in their results. Within a few weeks after the terrible explosion of dynamite which nearly destroyed the Murray Hill Hotel, the sides of the excavation in Park Avenue, between Thirty-seventh and Thirty-eighth Streets, which was supposed to be in solid rock, and was therefore not braced, suddenly gave way, allowing the soil to escape from beneath the foundations of several of the neighboring houses, letting the front walls of three of them fall. Unfortunate as the accident was, it seems to have been one of the casualties which could not have been foreseen. The whole neighboring region is a mass of rock, a sort of "bastard granite," as the contractors call it, slightly stratified. The stone is hard, and generally sound, and is constantly used for foundation work in the upper part of the city, so that, although the tunnel excavation was about forty feet lower than the cellar floors of the houses, anything like a "slip" would seem extremely improbable, if not impossible. As it proved, however, some unfavorable dip of the stratification, or, possibly, some water-bearing seam, favored a movement in just the direction in which it could do the most damage.

SO far as can be judged from the daily papers, there seems to be a little doubt whether the St. Louis Exposition will really be held next year. The disastrous financial failure of the Buffalo Exposition, followed by the disappointments of that at Charleston, have discouraged some, at least, of the St. Louis people, and it is argued, not without reason, that a postponement for a year would not only make it possible to organize the affair more carefully, but would give the public a chance to recover a little of its appetite for international shows, which now seems to be suffering from surfeit. Whenever the Exposition is finally opened, the Municipal Art Exhibit is likely to be one of the most interesting things in it to architects and engineers; and we may as well remark here that it is to be hoped that architects and engineers who want to see it will be enabled in some way to find it. As our readers remember, a splendid display of American municipal engineering work was made by the city of Boston at the Paris Exposition of 1900, but, perhaps because it did not fit accurately into any one of the official divisions of the exhibition, it was almost impossible to find it. As municipal art is neither a fine-art, like painting and sculpture, nor a branch of engineering, like sewers and tramways, nor a form of education or of public charity, it has no definite place in the usual scheme of exposition classification, and must be made conspicuous in its own way.

AS laid out by Mr. Albert Kelsey, who is, apparently, entitled to the honor of having first prepared the definite plan, the Municipal Art Exhibit is to occupy a circular space, surrounded by a boulevard, planted with trees in the most approved manner. On a square adjoining the boulevard is the railway station, and from this a paved street extends in a straight line to the "plaza," which occupies the centre of the model town. Around the plaza are arranged the court-house, town-hall and post-office. From the plaza radiate other streets, and special districts are set apart for "amusement" and "educational" centres, furnished with model theatres, school-houses and libraries. Possibly a model tenement-house may be shown; and it is likely that some of the accessory services of the Exposition, such as a hospital and fire-station, will form a part of the model city. In the way of detail, it is proposed to show different street sections, systems of sewerage, lighting and the other municipal services on the perfection of which the comfort of dwellers in cities so greatly depends; while as much as possible will be done to bring together beautiful suggestions in design, grouping and arrangement, not only of buildings, but of fountains, monuments, bridges, park planting, lamps and so on. It is hoped that a Congress of Public Art, like those of Brussels and Paris, and the one to be held this spring at Turin, may be called at St. Louis, and, if this is done, the Model City will form the most interesting exhibit yet shown on such an occasion.

AN idea of the great advance which has been made in artistic street-designing in Germany may be derived from the plan of the new suburb of Elberfeld, made by the city engineer of Elberfeld, in consultation with the city engineer of Cologne, and published in the *Deutsche Bauzeitung*. It seems that a majority of the proprietors of a tract of surburban land, by applying to the city authorities, may have a plan made for developing it, which will be carried out if they desire it. In this case, the owner of a hilly tract, southwest of Elberfeld, determined upon improving it, and employed private talent to make a plan, which, it is needless to say, showed the territory divided by straight streets, at right angles with each other. Luckily, they found reason to be dissatisfied with this scheme before they attempted to carry it out, and applied to the city engineer, who set himself at work to devise a plan with street-lines not only more "characteristic," as the Germans say, but better suited to the irregularities of the natural surface. Our American city engineers, whose principle usually is to lay out their streets first with a ruler, and then make the ground conform to them, will probably be shocked to learn that Herr Voss's plan, covering a tract of two hundred and twenty-five acres, has not a straight street or a right angle in it, except where a single highway, already existing, is utilized as a part of the new system. Naturally, the house-lots, the proposed boundaries of which are given on the plan, vary in depth, but the variation is not excessive. Three pretty little parks of indescribable shape are introduced, at nearly equal distances apart. Notwithstanding the irregularity of the ground, the variation in height between different portions being nearly five hundred feet, only one street has so steep a slope as one in twelve, most of them being much less, while the natural surface is very little disturbed. Not only are the streets, as might be supposed, highly "characteristic," but we find that an attempt has been made to lay them out in "soft curves," an expression which, we are sure, is wholly lacking in the vocabulary of American city engineers' offices; and it is interesting to note that the steeper ascents are intentionally curved in plan, "in order to conceal the steepness from the eye."

THE EMPEROR'S SUMMER PALACE.

As an introduction or, rather, as a foil to some account of a visit to Shanghai by Prof. Edward S. Morse which we are about to publish, which account deals with the simpler forms of domestic life and domestic architecture — somewhat after the manner of his "*Japanese Homes*" — we have thought well to introduce here translated extracts from the "*Journal d'un Interprète en Chine*" which appeared at greater length in one of the recent "*Reports*" of the Smithsonian Institution.

The writer, the Comte de Herisson, was not only the interpreter but the private secretary of General Montauban, the commander of the French contingent, and, though a very young officer, shows himself to have been a keen and intelligent observer, adroit in analysis and skilful in synthesis.

The sacking of the summer palace occurred October 8, 1860, and the burning of it was ordered by Lord Elgin on the eighteenth of the same month, after the Europeans had come to full knowledge of the atrocious way in which their diplomatic representatives had been tortured, mutilated and murdered. — EDS.

THE next day the march was resumed at dawn, and the ground became more and more difficult. Finally a long halt was made by the army at a distance of little over a mile from the northeast corner of Pekin. A few minutes later an orderly arrived from General Grant to inform the French Commander that, according to spies, the Tartar army had retired to Yuenmingyuen, the magnificent imperial residence, for the probable purpose of protecting the Emperor, who was thought to be still in this, his autumn palace. Yuenmingyuen is in fact the autumn palace, which all Europeans call — I cannot imagine why — the summer palace. General Grant announced that he was going to visit it, and begged his comrade to accompany him. Montauban, interrupting the conversation held with Lord Elgin, gave the necessary orders, and the march was resumed past Haitien, an unimportant town, where the palace in question is situated, which I, like the rest of the world, shall call, if you please, the summer palace.

The guide who accompanied Grant's orderly told us that the palace was about two miles off; but, these two miles being very much like the "short half hour" of our French peasants, we marched for two hours and did not reach the place. At last, after having made a dozen times the two miles announced by our guide, the French army arrived at Haitien just as the day began to wane.

Just as Versailles is an appendage of the palace of the great king, so Haitien is an annex to the palace of Yuenmingyuen. A broad street, flagged with granite, leads directly to the palace, crossing, 600 feet before reaching it, a monumental bridge thrown over the canal. It is then transformed into an avenue of venerable trees, bordered by houses inhabited by the mandarins of the Court when the Son of Heaven deigns to show himself on earth in his summer palace.

The first companies to arrive halted in front of the palace, and soon the whole army was massed on the grand open square, which served as the court of honor, and which had very nearly the dimensions of the Place d'Armes at Versailles, but with the additional advantage of possessing splendid shade-trees.

Before us rose the hermetically closed walls surrounding the palace, and stretching on either side beyond our vision. . . .

The great gate was opened, the first court was occupied by the Collineau Brigade, and for greater security the gates which opened into the interior of the palace were barricaded without and guarded.

The capture of the palace had cost us the wounds of M. de Pina and M. Vivenot, as well as those of two marines, one sheep, and the general's walking-stick.

The next morning the gates were unfastened and opened. All within was silent and deserted. General de Montauban penetrated into the palace accompanied by Generals Jamin and Collineau and Colonel Schmitz. I had the honor to follow these four officers.

The generals, from a feeling of delicacy, easy to comprehend, had wished that the first visit might be made in the presence of a delegation of English officers, whose troops were marching with us. None of these officers knew what had become of their general-in-chief and the army, and cannon were fired every five minutes for an hour on the great square, to indicate to our allies the place where we could be found.

We five Frenchmen were joined by Brigadier Pattle, Major Sley, of the Queen's Dragoons, and Colonel Fowley, and were preceded by a company of marines.

To depict all the splendors before our astonished eyes, I should need to dissolve specimens of all known precious stones in liquid gold for ink, and to dip into it a diamond pen tipped with the fantasies of an Oriental poet.

What struck me at first was this: Although built in a pure and elegant Chinese style, the summer palace furnished in its arrangement, its architecture, and even in certain of its details, singular reminiscences of the palace at Versailles, modified by the peculiarities of all Chinese constructions, which are never more than one story in height, having only a ground-floor, without attics or mansard windows, with nothing to separate the roof from the rooms on the ground-floor. This distant resemblance is not inexplicable.

The Jesuits, who played so important a part in China, who gave to it veritable Richelieus and Mazarins; the Jesuits, who remained in high honor as semi-sovereigns at Pekin until 1773, when their order was suppressed by Clement XIV; the Jesuits, as clever in administration as they are great in mathematics, who had in their order men having all talents and knowing all sciences, were in some sort the architects of the summer palace and the designers of the beautiful gardens.

At that epoch Louis XIV had sunk so many millions in Versailles that when he received detailed bills he ordered them to be paid and burned, hoping to conceal from posterity as well as from himself his royal folly. The echo of these splendors created by the Grand Monarch reverberated from country to country, transmitted by word of mouth throughout the world, and finally reached the ears of the Emperor of China.

The Son of Heaven found it strange and inappropriate that there should be on the earth a king who took the sacred emblem of the sun and who allowed himself treasures which he, the true Son of Heaven, had not secured. And what sort of a king? A mere kinglet, a man who governed a paltry handful of human beings, 25,000,000 souls, who was consequently only one-thirteenth of his own importance. And in this way, strange as the thing appears, Versailles gave birth, in some measure, on another continent, to the richness and magnificence of Yuenmingyuen. The palace was a long time in construction, and the Jesuits were succeeded by other missionaries, as artistic as themselves, who had but to embellish the original plans. But this is history enough; let us proceed.

At the end of the first court arose on three granite steps an immense hall, its naked walls unornamented save by a few inscriptions, and having no furniture but high-backed wooden benches. It was here that his subjects awaited the honor of approaching His Majesty. Behind the hall on the same level stretches a second court, which separates it from the audience-chamber; this court is furnished with vases of old porcelain, four or five feet high, which serve to hold a quantity of little trees, each queerer than the other. . . . Take, for example, an oak. It is 200 years old; it does not resemble a young tree; on the contrary, it is an exact photographic reduction of a huge and venerable oak of the forest, but it is only three feet high. It is a perfect dwarf, and by the side of it is a group of six trees of different species, growing a few inches apart, in a single vase, which are united at the height of three feet into a single trunk, which branches out a little higher, producing leaves impossible to classify — and, observe, the Chinese are not acquainted with grafting. These tricks are reproduced in all the large pots in varying forms. Generations of learned men have devoted their lives to the study of prócesses for cultivating these vegetable monstrosities, and presently, continuing our visit, we shall find on the shelves of ancient libraries the results of their studies, in well-labelled volumes.

We only gave a passing attention to the extravagant contents of these porcelain vases, of which the smallest would be worth 100,000 francs in Druot's auction-rooms, and we went straight into the first audience-room, which opened before us.

This hall forms one side of a quadrangle of buildings, in the midst of which is a garden and fountains; to the right and to the left are two other halls of audience and of ceremonies, and at the far end of the quadrangle the throne-room.

In the three halls first traversed we found most extraordinary treasures. We must bear in mind that the Emperor preserved in these palaces — transformed into a museum, or, rather, into a warehouse of riches — the most exquisite products of many generations of 400,000,000 human beings, of which he is the demigod, as well as all the tributes paid him by foreign nations, all the presents which fear or admiration had drawn from the great as well as the humble, all which had been confiscated from his rebellious subjects. We must bear in mind that in this immense Empire not a superior work of art was produced which did not naturally drift toward the Emperor, and not a treasure was discovered that did not fall into his hands of its own accord.

Here were gathered all the wealth in precious stones and fine fabrics presented by tributary princes, and all that the kings and emperors of Europe had sent to Hien-Fong and his predecessors, all the bric-à-brac and curiosities, as well as all the goods which the simple-minded merchant, wishing to obtain rights in a port, subtracted from his cargo to propitiate the Sovereign. Everything was preserved with care and equally honored, from a cloth of gold ornamented with pearls, which had come, perhaps, from the Sublime Porte, up to a doll that cried "papa" and "mamma," which a Marseilles captain had taken from his little daughter at Christmas and carried to China to "grease the palm" of the chief mandarin.

This multitude of treasures had overflowed the private apartments of the Sovereign and his wives and spread itself into these immense cathedral halls. The spectacle was at once extraordinary and dazzling — dazzling from the richness of the articles, extraordinary from their number and variety.

At length we reached the throne-room, placed on a platform approached by seven steps of beautiful granite polished like a mirror. It is completely separated from surrounding buildings. Its raised roof, extending at least three feet beyond the granite steps, is supported by two rows of ironwood columns, most artistically engraved and resembles those bamboos or engraved ivories which we in Europe use for tobacco-jars or match-boxes, but swollen to gigantic proportions. No two pillars were alike, and the scenes which were engraved in spirals around their shafts, as on the column in the Place Vendôme, were borrowed in part from national history, in part from legends, in part from celebrated romances and mythology.

The one against which I leaned, the only one of which I have a distinct recollection, pictured the life of the god of wine, whose skull is as high as the rest of his body. He is travelling, peacefully seated upon a buffalo, with a curved stick in his hand, and before reaching

the top of the pillar he must pass precipices, enchanting landscapes and caverns where monsters lie in wait, and finally go under a triumphal arch surrounded by pretty women. It is a lively sort of a journey for the good deity and a symbol of the imaginary voyages which his followers make after too copious libations in his honor.

On the shafts of these columns all the surface of the wood not removed by chisels is covered with lacquer of dazzling colors; on the capitals the imperial dragon twists and rolls himself into all possible shapes, holding in his claws escutcheons covered with mottoes.

From these columns, where our gaze has been agreeably arrested, it ascends to the roof, and there it meets a magnificent spectacle. The roof is covered with those shining yellow tiles made in the little village where we spent last night, the ridges and the eaves being of green tiles as brilliant as the yellow ones, producing an elegant and majestic combination of colors. At the four lower angles of the roof immense dragons of green *faïence* are crouching, inestimable products of the city of Hangtchoufou; the enormous beasts appear to be climbing up the ridges of the roof; they gaze at each other in pairs, their jaws open and their eyes staring.

Finally, at the two ends of the coping a marine monster in green-and-black *faïence* springs at another monster facing him, and gaily raises heavenward a three-metre-long tail, ending in a pinion which serves as a colossal double crest to the whole building, and gives to it a swaggering air, if one can apply such a word to a house.

In the sunlight, whose golden arrows are reflected in blinding array from these brilliant and gaudy surfaces, throwing its sparks into the eyeballs of the monsters, and its shadows into the abysses of their gaping jaws, the superb and magnificent building arises like an enormously magnified jewel.

Everything is clean and clear and intact in this masterpiece, over which the blue sky seems, at the coming of night, to close like a jewel-case with a blue-velvet lining. And the care of its preservation and maintenance is carried so far that wherever a wandering bird might place its tiny feet, it would find an invisible iron wire which would remove his desire to rest there.

The throne-room is entered by a great opening without a door. The interior might be seen from without were the view not intercepted by a screen of teak-wood, as big as the rood-screen of a cathedral — carved, inlaid, cut out like lace, and representing gods, and bounding men and horses — a room 160 yards long, 22 yards wide, and 17 yards high; such are its temple-like dimensions.

The throne faces the screen and is raised upon ten steps; it is a mountain of cushions and silk mattresses, in a niche nearly 25 feet wide, itself cut out of an immense lattice-work wainscoting, like an openwork alcove in the wood of the choir of one of our old cathedrals.

The hall is well lighted throughout, for the windows are close together, and furnished with ventilators, shades and blinds, permitting the passage of refreshing air no matter what the position of the sun. On piers between the windows, frames of sculptured woodwork surround pictured panels.

There is scarcely any furniture; behind the screen is a little altar facing the throne, on the right of the imperial seat a table and an arm-chair of teakwood. On the table are a golden tray, some writing brushes, a saucer of vermilion, and some paper on which is traced characters in vermilion — it is the interrupted correspondence of His Majesty. On the small altar rest two incense-burners of jade, some porcelain saucers, on which, in the absence of the Emperor, are placed fruits, tea and flowers, offerings addressed to his spirit, that, in Chinese belief, is always present in these places.

On either side of the throne, in the corners of the hall, are two doors, each leading to a kind of small saloon or oratory; that on the right communicating with the private apartments of the Sovereign; it is called the *Tien* — heaven.

The walls, the ceilings, the dressing-tables, the chairs, the footstools are all in gold, studded with gems. Rows of small gods in massy gold are carved with such wonderful skill that their artistic value is far beyond their intrinsic worth.

There, on supports of jade, are two pagodas of enamelled gold, as large as corn-bins, with seven superposed roofs, and from each pear-shaped pearls hang like so many bells. In among the gods are European clocks of every description. Two of them are of the beautiful Louis XVI style and are models of good taste, beauty and fine workmanship; alongside are more incense-burners, torches, candlesticks, golden boxes, snuff-boxes embellished with precious stones and enamelled miniatures, a jeweller's fevered dream.

In the other oratory to the left, which resembles the interior of a monstrance, are gathered all the articles for daily use of the "Son of Heaven," when occupying the throne-room; his tea-service, his cups; his pipes — the bowl of gold or silver — the long tubes enriched with coral, jade, rubies, sapphires and little tufts of many-colored silk; his ceremonial chaplets of rows of pearls as large as nuts, which are spread across his august breast, though their whiteness is not quite perfect. Here are his speaking-trumpets of silver-gilt, used at times to swell his voice to thunder tones for the benefit of his prostrate subjects. On wall-cabinets are a great many little silver blades, with rounded ends, nearly half an inch thick, two inches wide and eight long, looking a good deal like our thermometers; these bear engraved characters, the chiselled lines being filled with gold. Etiquette requires you not to speak to the Sovereign, not to even lift your eyes to his sacred person. If, however, he should ask, "What time is it?" how can you reply without speaking or looking at him? With bowed head one of the silver tablets on which is inscribed the particular passing minute is presented to him; he glances at it and learns what he needs to know. It is very ingenious, but for my part I should prefer a good watch.

I shall not attempt to portray the wonder and admiration of the "barbarians" who penetrated into these precincts. Involuntarily we spoke in low tones, and began to walk on tiptoe on seeing before us such a profusion of riches for the possession of which mortals fight and die, and which their owner had abandoned in his flight as indifferently as a citizen closes the door of his house, leaving his mahogany bureau exposed to the chances of war. All was so natural, so familiar, so commonplace to him that he did not even try to save these treasures.

Behind the throne-room, stretched over an immense space, in the midst of gardens, are the private apartments, likewise crowded with objects of luxury and beauty, but on the whole less extraordinary, for between the sleeping-room of an emperor and that of a private person there is less difference than between a throne-room and a parlor.

In the rooms of the Empress, the walls of the closets of the secretaries are furnished from top to bottom with pigeon-holes, in which, one above another, like files of lawyers' briefs, are red boxes of old lacquer of Pekin, wonderfully engraved in *intaglio*, containing ornaments, necklaces, and bracelets in pearls, in jade, in precious stones, tiny rings for feminine fingers, and huge ones of jade, worn by men when they draw the strings of their bows.

Boxes not holding ornaments already mounted are crowded with artistic objects, with materials to be transformed into jewels, with unique specimens of transparent jade, of rock-crystal, of milky jade, of moss-agates, of uncut diamonds, of precious stones still in their natural state; tea-services, cups, saucers, a regular bazaar — not one where everything is quoted at 19 cents — but rather a bazaar where everything is worth 19,000 francs. On opening one of these boxes, it appeared to send out sparks and sheaves of light.

Beyond, great wardrobes of old lacquer set into the walls of the room contain the garments of the Empress, both those for daily use and for ceremonious occasions. There was enough to dress, from head to foot, 10,000 princesses from the "*Arabian Nights*," so that it would be impossible for the Caliph of Bagdad, a judge in such matters, to find occasion for changing the position of a single pin or to alter their arrangement. All is of silk, satin, damask, fur, with embroideries sometimes as delicate as spiders' webs, sometimes as heavy as those on bishops' copes; it is a brilliant display of birds, butterflies, and flowers fresher than those in the sun, with diamond dew-drops in their perfumed calixes.

Here and there footstools of strange shape allow the ladies-in-waiting to reach the high shelves where the toilets are, and offer nest-like cushions to their little crippled feet.

His Imperial Majesty, as every one knows, does not content himself with a single wife. He has concubines, whose quarters are opposite his private apartments. These ladies, into whose rooms we throw a passing glance, our powers of attention being already wearied, are apparently almost as well cared for as their Sovereign, and drink their tea from cups almost as precious as his own. When the Son of Heaven takes a cup of tea here he must perceive no difference.

At last we have finished this endless fairy story and find ourselves face to face with nature, with fountains and with foliage. What a magnificent park! It is immense, with high walls extending about eight and a half miles around it. Those who designed it took special pains to arrange picturesque views, giving impressions which were sometimes gentle and tender, sometimes savage and theatrical; and they succeeded.

But they assisted nature by architectural effects also, and this park of Yuenmingyuen (literally, "residence of the original splendor") contains a little of everything — isolated palaces, temples, pavilions, pagodas, pyramids, porticos, colonnades, artificial mountains, grottos, lakes, rivulets, islands, groves, labyrinths, observatories and kiosks. The artificial rock-work, so fashionable among us a few years ago in Paris gardens, is here — immense, striking, monumental and unique.

Here, for instance, is a mountain built up of rocks; in niches cut in its sides are images of all sorts of infernal divinities, who grin and squirm in the midst of unheard-of vegetation. It dominates the entire park, its summit is crowned by a little pagoda, about 25′ x 20′, surmounted with roofs entirely of white porcelain, decorated with stars; it is dedicated to the Chinese Virgin, Koua Him, who, from this culminating point, seems to extend her protection over all the palaces lying at her feet. She is represented by a statuette of gilded bronze, seated in the midst of a lotus-flower; on each side watches a fully-armed warrior; these two sentinels are engaged in hideous contortions and in making horrible faces.

On the right of this artificial mountain, following a labyrinth whose tortuous paths easily lead one astray in a space of 50 square yards, rises a large building; it is the imperial library. Its roof, with yellow tiles, resembles that of the throne-room, and, like it, is peopled with a menagerie of black *faïence* dragons chasing other chimerical monsters.

The hall, 40 feet high, 30 wide, and 120 long, has its walls lined with cases in which are most curious and ancient manuscripts. In the hall are tables and arm-chairs for studious visitors, and two small altars, one to the north and the other to the south, on which are still slowly burning perfumed incense-sticks in honor of Confucius and of Lao-Tzeu, whose portraits are reproduced on large silken banners suspended here and there.

Here are the grottos, deep, crooked, and full of statues of gods

and animals; some have the entrance curtained by hanging vines; in others a crystal cascade falls from an upper basin and loses itself murmuring through the turf. Here are the lakes; in the centre of the largest is a small palace, which we have neither the time nor courage to visit, but which I beg the reader to keep in mind; he will soon learn why. This palace, built on an island, whose heaped-up soil scarcely rises above the surrounding water, seems to emerge from the bottom of the lake.

On the border of the lake, to the left, is a large building of carved and precious woods, entirely smothered under the vines twining around it, climbing its top, and winding in flowery plumes about the tails of dragons scaling its roof. It is a coach-house, and contains the carriages of gilded and carved wood, with doors covered with Vernis Martin, interiors lined with Genoa velvet, great carriage-lamps of chiselled silver, with thick and heavy cloths like women's dresses at the Court of Louis XIV, and ornamented with pendants of gold and of silk — which had been sent to the Emperor of China by George III, through Lord Macartney at the end of the preceding century. In this memorable embassy, the English, with the object of serving the interests of the East India Company, consented to pay tribute to the Emperor of China. These carriages, their magnificent trappings stretched on wooden horses, were never used; they were covered with dust and could not have been often seen.

Alongside of the stable was the landing-place of the imperial pleasure-boats; its roof of yellow tiles extended above the lake. There was the bark of His Majesty, one for the Empress, others for royal princes, and still others for high mandarins. There was the fishing-boat of the Emperor, gilded and lacquered, and still furnished with his paraphernalia. Within this the Son of Heaven gave himself up to fishing among the innumerable varieties of fish which the Chinese fish breeders, foremost in the world, had created for him, but he cannot have abused this sport, for the fish appeared to us to be quite tame, and as they had no patrotic spirit, they came to the edge of the lake to gaze at the barbarians and shamelessly ate their bread. There are goldfishes a foot long, whose name alone describes them. Here are redfish, cousins to those that people the basins in the Tuileries, and here are little marine monsters, all head, with eyes as large as those of a man; while others resemble the sea-horse, a fish venerated by the Chinese under the name of water-dragon; to us they are hideous, but to them, beautiful.

A little farther on rises a tower, an exact reproduction of the famous porcelain tower of Nankin, its numerous roofs marking as many stories. To reach it one has to pass in front of a pagoda built in honor of Buddha; and the statue of the god seated on a low pedestal, his legs crossed in Turkish or Chinese style, is not less than 65 feet high, while a staircase which runs along the interior wall of the pagoda permits climbing to the level of his head of frizzled hair, his knees being reached at the first story, his navel at the second, and so on. This very ancient statue is of gilded bronze, but time has impaired the gilding; the half-closed eyes of the god are of silver, their pupils of iron; from one knee to the other at the base the statue measures 45 feet. Two gigantic incense-burners and one altar are in this pagoda, which has been constructed solely as a shelter to the statue.

Our presentation to this enormous gentleman terminated our visit to the summer palace. It had lasted several hours. We returned worn-out, exhausted, our eyes burning from the sight of all this gold and this splendor, with aching heads.

The general-in-chief placed sentinels at all the entrances to prevent any one from penetrating the palace before the arrival of our allies, and he assigned two captains of artillery, MM. Schelcher and de Brives, to see that the order was strictly carried out.

To add to the effect of our signal guns, Brigadier Pattle had sent numerous troops of cavalry in every direction, who finally met General Grant with his army and brought them in at noon. On his arrival General Grant went into the palace and saw with his own eyes that everything was intact.

PARIS

GREAT UNDERTAKINGS BY THE MUNICIPALITY. — PROPOSED NEW BRIDGE OVER THE SEINE. — THE EQUITABLE INSURANCE BUILDING. — THE THIÉRY BEQUEST TO THE LOUVRE.

WHAT will Paris look like in fifty years — even, perhaps, before that? It will be larger surely, possibly it will be uglier. In any event, if the projects already voted by the Municipal Council are carried out, it will have lost the little that is left of its picturesque and historical beauty. Under the Second Empire, Haussmann, the Prefect of the Seine, drew up a plan for the embellishment of the city, which, it must be allowed, was intended to do away with certain old quarters that really encumbered the centre of Paris. It is to him that we owe the widening of the present streets, the cutting of the Avenue de l'Opéra, the boulevards on the left bank, and the creation of all the wide and well-ventilated streets upon which handsome and hygienic modern buildings have replaced the old and unhealthy structures. These are changes which hardly any one dares to regret. This necessary disembowelling perforce drew after it the disappearance of certain picturesque corners and provoked certain regrets on the part of artists smitten with the love of old things and the admirers of old Paris. But there still was left the Marais, the Ile St. Louis and the Ile de la Cité, where certain relics worthy of their love and adoration were still to be found.

Alas! The Municipal Council has just dealt them a cruel blow. Not content with its recent decrees taxing land not already built on, thus, consequently, assailing private gardens and provoking the destruction of the little that is left of verdure and freshness in Paris, it has just voted in favor of certain works which, if carried out, menace one of the classic beauties of the capital. This tax on land not built upon, of which the *American Architect* spoke in its issue for the 30th of November last, may be, and probably will be, annulled, but the misfortune would be irreparable if a sequel should be had to the vote passed by the Municipal Council in the last month of the past year.

Among the works proposed for Paris, there are some of great utility. The demolition of the fortifications, for example, is an absolute necessity. Now no longer answering to the real needs of defense in case of war, they render unfruitful a considerable superficial area of land the sale of which would create for the city enormous revenues. So the suppression of the fortifications on the west and northwest of the city is a burning question just now. That is to say, on the side where the population seems most inclined to spread. The city would equally find serious advantages in the sale of a large part of the Champ-de-Mars. One scheme, a very ingenious one by M. Bouvard, architect of the Services of Architecture, consists in at length demolishing the Gallery of Machinery, and creating a long and wide avenue, bordered by gardens, on the axis of the Champ-de-Mars in front of the École Militaire. The land bordering on each side of this avenue would be sold under the pledge of having built there magnificent buildings.

These schemes are very attractive; so, too, is the completion of the Boulevard Haussmann, for a long time demanded, and also that of the Boulevard Raspail, on the left bank. Unfortunately, they don't stop here, and there is now a question of the prolongation of the Rue de Rennes, under conditions which are absolutely disastrous.

This prolongation of the Rue de Rennes carries with it, in fact, the demolition of a portion of the Palace of the Institute, and, what is still more unfortunate, the building of a bridge over the Seine, the central pier of which would have to rest on the extreme point of the Ile de la Cité. This scheme, in fact, was an item in Haussmann's plans, in so far as concerns the demolition of the Palace of the Institute. Without the least compunction, this vandal prefect had the intention of sacrificing both wings of the Palace; but the Commission Supérieure des Bâtiments laid a protest before the Emperor. In 1860, the latter visited the Bibliothèque Mazarine, and, thanks to M. de Sacy, the threats of M. Haussmann were not carried out and the Institute was saved. To-day, the administration of the city again takes up the scheme. They modify it and ameliorate it in the sense that the entire façade of the Palace is to be respected. The buildings on the grand courtyard in the rear will alone be sacrificed, in such a way as to allow a new street to be cut between the Palace of the Institute and the Hôtel de la Monnaie. But what is to become of all the services of the Institute now arranged in a retiring and quiet fashion, far from the noises of the street, in such a way as to assure the calm and retirement necessary to our savants and our artists? The library and halls of study will have to be rearranged and brought out upon the façade on the new street, with its animation and noises. Hence, protestations have not tarried, and the Academicians are ready to defend their home.

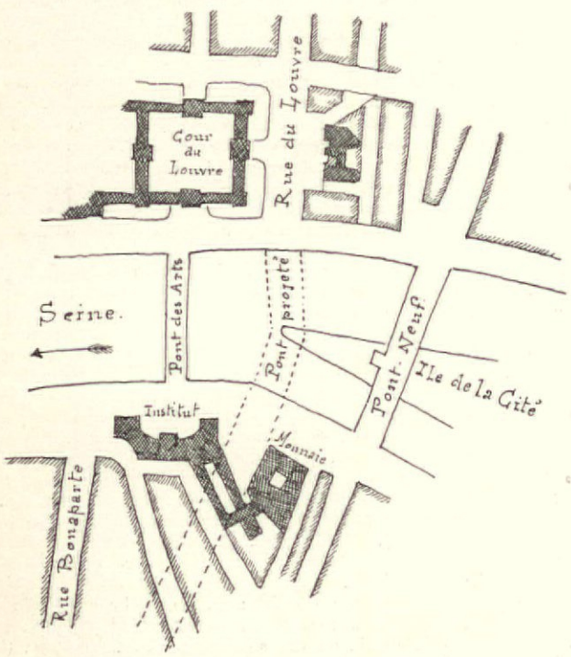
If this careless disregard of the rights of the Institute is blamable, what shall be said of the construction of a new bridge, which is one of its consequences?

In the eighteenth century, a distinguished traveller professed that the three finest views that he had ever encountered in his long journeyings were that at the entrance of the harbor of Constantinople, that from the port of Goa, in the Portuguese Indies, and, finally, that from the Pont Neuf, at Paris. There is little literature and few artists who have not paid their tribute to this vision of old Paris, — Notre-Dame, the Sainte Chapelle and the Palace of Justice, silhouetting their *flèches* and towers above the verdant point of the Ile de la Cité and the majestic arches of the Pont Neuf. In the transparent mists of the morning, in the warm caress of the setting sun, it is always a superb picture and one of the picturesque scenes most admired by strangers.

Can one imagine this panorama cut athwart by a modern bridge? Can one suppose this admirable perspective of *quais* and the banks of the Seine barred forever? This little verdant island suppressed and replaced by monumental and heavy piers? Do not allow the example of the Alexander III Bridge to be invoked, which also was criticised before its execution. Let no one bring forward reasons of sheer utility.

The site of the Alexander III Bridge cannot be compared with this of the projected bridge, which must be placed at the very spot where the Seine is widest and most beautiful. As to utility, that is a matter open to discussion. The end aimed at is the facilitated communication at this point between the left and right banks in the line of the prolongation of the Rue du Louvre. But even though this end cannot be attained save by means of such sacrifices, is it not

allowable to demand of practical exigencies certain concessions in favor of art and the æsthetic beauties of the city? A bridge is necessary? Well, nothing is easier than to build one in place of the Pont des Arts, a simple foot-bridge now, impassable to vehicles. On the axis of the Palace of the Institute and the arcades of the court-yard of the Louvre, this bridge, with its sufficient widenings at each end, and the widening which would be necessary in its length, would



Plan indiquant le tracé du nouveau pont projeté.

only compel an insignificant detour for one desiring to enter the Rue du Louvre.

As to the prolongation of the Rue de Rennes, it could be made much more economically by a widening of the Rue Buonaparte, which would allow the integrity of the Palace of the Institute to be absolutely respected.

How simple this is! It is much too simple to be approved by the Administration. But, nevertheless, the scheme voted by the Municipal Council, and which, happily, must be discussed in the Chamber of Deputies, has made a great number of people indignant. In the Municipal Council itself, several have protested; several journals voice cries of alarm and call upon the societies of artists and upon the commissions charged with defending the monuments of the past. Let us hope that these efforts will result in something and succeed in fending off an act of real vandalism. And, in this connection, is it not regrettable that the societies which are now called upon to protest against this scheme should not, in the first place, be consulted, before votes of this importance are carried? It would be interesting to have, before reaching decisions of this character, the advice of competent artists and architects. This is done in Vienna, and, I believe, in certain other cities of Europe. It would evidently be necessary that a special commission should be composed of persons very independent, while having incontestable authority. It is this attribute of independence which is too often lacking. So, in the matter which occupies our attention to-day, the Société Centrale des Architectes was invited by some of its active members to publicly protest before the administrative powers against the construction of the projected bridge and the partial demolition of the Institute. Surely, the proposition would have rallied numerous suffrages when it was perceived (Oh, irony!) that the president of the said Society was the very one entrusted, as architect of the Institute, with the study of the project! He could not, then, protest, even in the name of his confrères, against the very work which he was charged with carrying out! But, isn't it amusing?

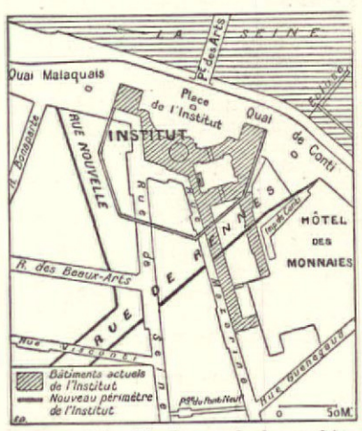
Amongst the other schemes interesting the capital and its monumental wealth is one which, in a private capacity and aside from all matters of public administration, is not less important. This comes to us from the United States in the way of a grand insurance building — the Equitable. For several years past we have had on the boulevards a very rich and sumptuous building, erected by the New York Life Insurance Company.

The Equitable of the United States, already the proprietor of two buildings on the Avenue de l'Opéra, has just acquired the corner of the Place de l'Opéra included between the Rue de la Paix and the Boulevard des Capucines. The buildings now standing occupy an area of 1,197 metres, and their façades, developed, measure 99.5 metres, of which 53.5 are on the Boulevard, 19 on the Place de l'Opéra and 27 on the Rue de la Paix. The price paid by the Equitable is 8,000,000 francs. It is, therefore, a very important affair, all the larger since it is the intention of the Company to demolish the present buildings and build in their place new ones for the composition of which a competition is to be opened to all French architects. This was what was done with the New York building. If the results of the new competition are as satisfactory, we shall have, on the Place de l'Opéra, a new palace of splendid elegance adding to the richness of this place a unique framing such as our Grand Opéra deserves.

If things go on in this way, it is America, apparently, which is going to rebuild Paris!

While all these schemes are being elaborated with a view to its architectural transformation, Paris finds the collections at the Louvre enriched by a princely gift. A Moor, of French origin, M. Thomy Thiéry,[1] has just died, bequeathing to our National Museum a collection whose richness is beyond words. Never, since the time of the Lacaze bequest, which fills an entire hall at the Louvre, has a more princely gift been offered. It includes, in fact, a marvellous collection of our French masters of the nineteenth century, of almost the entire work of the sculptor Barye, in models, and a superb collection of furniture in Gobelin tapestry, all estimated at a value of 9,000,000 francs. The cause of the formation of this collection is sufficiently odd. Very much smitten with the school of painting which stretches from 1825 to about 1860, Thiéry adopted the programme of having in his collection twelve paintings by each of twelve artists. His choice rested on Delacroix, Decamps, Millet, Théodore Rousseau, Corot, Tryon, Isabey, Jules Dupré, Diaz, Daubigny and Meissonnier. As the twelfth master, the collector fixed upon the sculptor Barye. But time was too short for him to be able to completely carry out his programme, and his collection is composed of 12 Corots, Jules Duprés and Diazes, 13 Daubignys, 17 Decamps, 11 Delacroix and Tryons, 6 Théodore Rousseaus, 6 Isabeys, 6 Millets and 5 Meissonniers. Barye, unfortunately, is represented only by a single finished piece — "The Two Lions." In all, then, there are 115 canvases and 1 piece of sculpture. It is not a bad legacy! When we shall actually come into possession of these *chefs d'oeuvre* is unknown. Perhaps not immediately, as administrative formalities in France take time!

We find from an account in *L'Eclair* that the question of throwing a new bridge across the Seine has apparently been settled in the negative, largely through the intervention of the Commission du Vieux Paris and because of the general feeling that it was necessary to preserve the historic view from the Pont Neuf and the refreshing bit of verdure to which our correspondent refers above. The Prefect of the Seine, however, gave the matter a turn of great significance, for he declared that the Commission du Vieux Paris was not merely the zealous guardian of the treasures of past ages, that it had not merely the narrow function of jealously watching over the riches of the past, but that it had a more vital mission in a higher and larger degree. Its real duty was to associate itself with the incessant transformations going on in a great city where the appearances of things are inevitably submitted to unceasing progress. The Paris of the Commission du Vieux Paris is not a thing which cannot be varied from. The necessities of the city's active life lay on it the obligation of constantly rebuilding upon its own ruins. The ideal effort, therefore, is to reconcile the feverishness of contemporaneous demands with the serene calmness of the dead centuries. The way to really defend Old Paris is to allow her to lend herself, in the happiest way possible and without damage, to the decoration of the New Paris. The prefect, therefore, promised to always submit all questions to the consideration of the Commission du Vieux Paris whenever the embellishment of New Paris was under discussion.



The question of the new bridge being thus disposed of, the changes of the street-lines, in so far as they affect the Palace of the Institute, suggested by M. Bouvard, the architect in charge of the building, appear to have been adopted, as shown in the annexed plan, and M. Bouvard declared plainly that he created these two streets in order that the erection of a new bridge might be avoided. The

[1] The Paris *Figaro* gives some interesting details concerning M. Thomy Thiéry, whose gift of modern pictures, worth millions of francs to the Louvre, has been recorded above. He was born in 1823, at Port Louis, in Mauritius, and educated in Paris. He went back to Mauritius in 1848 and continued to work the sugar plantations left him by his father until 1875, when he settled in Paris. His hobby was picture buying, especially pictures of the school of Corot, Dupré, Millet and Daubigny. According to common report he spent about $800,000 upon his collection. He was represented at every important picture sale of the last thirty years, whether in France, England or this country. During the last ten years of his life he was afflicted with partial paralysis, which confined him to a chair and finally to a species of litter which was moved from place to place in his gallery, so that he could always have some of his masterpieces before him. The sole condition of his gift to the Louvre is that the collection shall be kept together in a gallery to be known by his name.

circulation in this way will be divided into two streams, one flowing towards the Pont Neuf and the other towards the Pont des Sts. Pères. The possibility of getting along without the new bridge is further strengthened by the fact that the Metropolitan Railway is to pass under the river, in that way connecting both banks. This solution has received the approval of the Commission du Vieux Paris and this approval is to be considered as its contribution to the decoration of New Paris. But, at the same time, in order that there may be no misapprehension as to its convictions, it has renewed its aspiration that no bridge should be thrown across the Seine between the Pont Neuf and the Pont des Arts, and this is its contribution to the preservation of Old Paris. As for the Palace of the Institute, the façade towards the river remains unchanged, and by the new disposition of the streets it secures a larger area of ground than that which it abandons to the new thoroughfares. — EDS.

THE LATEST FROM THE ROMAN FORUM.[1]

IT is as nearly as possible three years since the era of new discovery in the Roman Forum was opened by Signor Giacomo Boni. Every year has brought fresh results, and though, as time goes on, the area which still offers possibilities for enlightened excavation is becoming more restricted, there is no reason to suppose that the era is nearing its close. Still, the character of the work is gradually changing.

Startling discoveries like those of the Lapis Niger, the Fons Juturnæ and the Basilica Palatina (Santa Maria Antiqua) are no longer within the bounds of probability, but an immense field for patient investigation lies open in the nooks and corners of the Forum and in the apparently meaningless spots which lie between the sites of the chief monuments. Ritual pits, deposits of sacrificial ashes, old drains and shapeless blocks of concrete become under Signor Boni's patient and thorough analysis so many leaves in the Book of the Forum which the world is entitled to expect him to write. This kind of work is more tiresome to onlookers than the excavation of famous spots, but it is equally useful because it helps to confirm old impressions, to correct assumptions which previously seemed justified, and to pile up a mass of evidence from which archæologists will be able to draw sound conclusions.

The most picturesque discovery of the year, or rather the one which appeals most strongly to the imagination, is that of the subterranean galleries running north and south and east and west under the heart of the Forum, in the space between the Black Stone and the Basilica Giulia, immediately in front of the Rostra. These galleries are 10 feet high and 4 feet broad. They lie about one foot below the surface of the Forum, and communicate with the air by openings large enough to admit of the passage of a man. At distances along the galleries there are square chambers large enough to admit apparatus for working a kind of windlass, and the sides of the openings are worn down by rope-marks — a sign that heavy objects must have been raised and lowered through them. Some of the elm beams which served as windlasses were found in the galleries. The most probable explanation is that the galleries were used as an armamentarium during the Cæsarean games which took place in the Forum prior to the construction of the amphitheatre. The most probable date of their construction is about 45 B. C., during the lifetime of Julius Cæsar; and the Aretine vases, the coins and other datable objects found in the galleries show that they must have been abandoned during the reign of Augustus.

For the present the examination of the galleries has had to be suspended owing to the infiltration of water, but as soon as the municipality has arranged a proper outlet for the Cloaca Maxima, operations will be resumed. It is easy to imagine the bustle which must have gone on in these galleries during the Cæsarean games when scene-shifting and stage-carpentering had to be done or when banquets had to be served. The galleries could certainly contain several scores of workmen at a time.

Another important discovery of the year is the Volcanale, or original rock, cut perpendicularly so as to form a kind of rostrum near the Senate House before the regular Rostra were constructed. The rock still bears traces of the red plaster with which it was covered in the time of the kings. This discovery has completed the series of Rostra which represented the tribunals of the common people. Of the curious arched chambers under the Imperial Rostra descriptions have previously been given, and Signor Boni's hypothesis that they served as a repository for the bronze rams or rostra of the enemies' captured ships is still the only credible explanation of their purpose.

In other parts of the Forum, excavations have led to the discovery of the site of the Temple of Jupiter Stator, near the Arch of Titus, and to the unearthing of the bases of the arch itself so that its original proportions may be seen and its history imagined from the different levels of the marks made by wheels as they rubbed against its sides. At the same time work has been pushed forward behind the Church of Santa Francesca Romana, where the graceful arcades erected in the fifteenth century on the foundations of the Temple of Venus and Rome have been rendered visible. The old cloisters and rooms of the convent are being converted into a museum for the principal objects found during the Forum excavations.

Much careful reconstruction has been done in the Palatine Basilica, commonly known as Santa Maria Antiqua. As inevitably happens whenever buried frescos are brought to light, their freshness gradually disappears, and it becomes impossible to form an idea of their original beauty unless they are carefully damped with a wet cloth or brush. As this process, if open repeated, would naturally damage the frescos, Signor Boni has had them carefully copied by special artists, who have succeeded in reproducing the frescos with perfect color and accuracy. These copies will be placed in the new Forum Museum at Santa Francesca Romana, where they will be accessible to all visitors. Signor Boni is also bridging over the gap which now exists in the winding tiled slope that leads from the side of the Palatine Basilica up to the Palatine Hill. This operation is one of great delicacy, but when completed it will enable the true relation of the Palatine to the Forum to be understood, especially after the Vicus Tuscus had been thoroughly cleared of earth and the Temple of Castor and Pollux completely isolated. It will then be possible to clear the whole of the foot of the Palatine Hill and to pass along it, by the baptistery of San Theodorus and the Byzantine Church of San't Anastasia, to the Circus Maximus.

In comparison with undertakings of such importance the discovery of the splendid mosaic pavements of the House of the Vestals and of other details of the ritual and sacerdotal edifices of the Romans seem almost insignificant, but they prove the theories of some earlier excavators concerning the asceticism of the life and dwellings of the Vestals to be far from the truth.

Until Signor Boni has completed the series of reports to the Government which he is now writing it will not be possible for others than professional archæologists to form a connected idea of the light thrown by his discoveries on the life of the Forum as a whole and its place in the organization of the Roman State. In the meantime the Italian Government may be congratulated on possessing so intelligent and indefatigable an official and on having seconded his efforts to elucidate one of the most interesting problems of human history.

ST. PAUL'S CHURCH, NANTUCKET, MASS. MR. JOSEPH W. NORTHROP, ARCHITECT, BRIDGEPORT, CONN.

THIS church is being built by Miss C. L. W. French, of Boston, as a memorial of Mr. Jonathan French, one of Boston's old time merchants. The material is light buff-gray granite. The roof is of black slate. The west window, also five chancel windows, are by Tiffany, and are memorials of relatives of Miss French. The interior is finished in ash and oak. There are columns of wood, with richly carved capitals between nave and aisles. The cost is about $35,000.

NOTES & CLIPPINGS

TUNNELLING A VENETIAN CANAL. — The Italian Government has decided to construct a tunnel connecting Venice with the adjoining island of La Giudecca. — *Exchange.*

THE CLEVELAND, O., GROUP PLAN. — Further steps have been taken in the last few days in the advancement of Cleveland's scheme to reconstruct the public buildings of the city on the "group plan." A site has been chosen for the execution of the scheme, and friction between the city and county authorities, which threatened the success of the project at one time, has been overcome. As now decided, the municipal, county, and Federal buildings will be grouped about a court of honor, some 350 feet wide, and long enough to stretch from Superior Street north to Summit Street on the lake-front, a distance of five blocks. Altogether, something over eight squares of the city will be given over to this scheme of architectural embellishment on a grand scale, in addition to the land on which the Federal Building will stand and the abutting square already used as a park. In other words, practically ten city blocks will be devoted to the buildings of the group and the parks and courts within and about it. On the south, it is proposed to give the place of honor to the new Federal Building; on the north, next the lake, where the new park to be created will be but a street's width removed from the Lake View Park, which stretches along the water-front, space has been allotted for a court-house, in deference to the desires of the County Commissioners that their building be in as conspicuous a position as possible. Along the sides of the court of honor thus bounded at its ends there will be a library, music-hall, City-hall, separate buildings for the Chamber of Commerce and Board of Education, and also, it is hoped, a gallery of art. Expropriation will be the necessary method for obtaining much of the needed land, and legislative authority is required before actual work can begin. The improvements will cost complete, it is supposed, about $16,000,000, but the work will be carried out so gradually that this expenditure will be spread over a number of years. Part of the necessary land is already owned by the city, as the central boulevard or court will be where Wood Street now is, and to some extent park-lands will be used. Not without reason, the people of Cleveland are inclined to expect great results from this Hausmannizing of the principal portion of their town. Carefully carried out, the plan offers great possibilities of civic and artistic distinction. Too many cities, especially in their central sections, have been allowed to grow up in haphazard fashion; too few have ever risen on the lines of a preconceived and judicious plan. While lacking the eyesores which make parts of the national capital hideous, Cleveland promises to develop beauties which in many respects may rival even those of a reconstructed Washington. — *N. Y. Evening Post.*

STOOP PROJECTING BEYOND THE STOOP-LINE. — George H. B. Hill, the owner of the premises 25 West Thirty-fourth Street, on May 19, 1898, sold the property to Mitchell A. C. Levy. The latter paid $1,500 on account, and the searching of the title cost him $240. As a result of the search Levy discovered that the stoop of the Thirty-fourth Street building extended beyond the stoop-line 15 feet 8 inches, and constituted an unlawful encroachment upon the street, and was liable to be removed at any time by the municipal authorities. Levy held that the extension made the title defective, and brought an action asking that a just deduction be made from the purchase-money because of the defective title and the incumbrance and encroachment mentioned. The Court held that this suit could not be maintained, and then Levy sued to recover the deposit-money and the cost of searching the title. This also fell through, Justice Patterson in his opinion saying: "The projection of a stoop beyond the line of a city street is not necessarily unlawful, and the question as to whether it is can only arise between the municipal authorities and the owner of the building, and that such encroachment does not constitute a defect in the title. The stoop in the present case has occupied its present position for thirty years and upward without objection on the part of the municipality or of adjoining property-owners or any other persons. The contingency that its removal will ever be compelled by the municipality or any person having authority in the premises is so remote as not to be within reasonable contemplation. These decisions are authoritative of the questions presented and result in the conclusion that plaintiff is not entitled to recover the sum sought to be recovered in this action." On a motion for a new trial upon exceptions the case came up before the Appellate Division of the Supreme Court, and Justice Hatch, in his opinion, concurred in by Justices O'Brien, McLaughlin, and Laughlin, filed recently, granted a motion for a new trial. To this finding Justice Van Brunt dissented. — *N. Y. Times.*

JOHN RUSKIN AND NEWMAN HALL. — While his church was building, Mr. Newman Hall had an amusing bout with Mr. John Ruskin. He went and asked the seer's advice as to how to erect a church which should not only be commodious, but beautiful, not only sheltering from rain and sun, but inspiring happy thoughts and holy emotions. He replied — as he had already written — "that we should not build up stones, but gather together a few people who would not steal or tell lies." "I said," writes the pastor, "that we had many hundreds of such, and needed a building where under shelter they might worship and be taught. He repeated his opinion, and I said I had made a mistake in troubling him, as I thought I was speaking to the author of the 'Stones of Venice.'" Whereupon Mr. Ruskin made the singular reply: "No, you are not. Every one who does something in teaching men passes through three stages of life. At first he teaches what is inaccurate; then he unlearns it, and lastly he teaches the Truth — which stage I have now reached." That was in 1872. — *London Chronicle.*

PROPOSED STATUE OF L'ENFANT. — Representative McDermott of New Jersey has introduced a bill in the House appropriating $50,000 for the erection of a statue in the city of Washington in memory of Major Pierre L'Enfant, who prepared the plans of that city. — *Exchange.*

THE WALLS OF AVIGNON. — The Paris correspondent of *The Times* says Edouard Aynard attacked the Government in the Chamber of Deputies recently, in the course of the debate on the Fine-Arts Estimates, for allowing the municipality of Avignon to demolish a section of the ramparts. M. Aynard also condemned the Commission on Historical Monuments for allowing the demolition. The portion of the ramparts demolished consists of about 1,200 feet of wall opposite the railway-station. It is not ancient, having been rebuilt by Viollet-le-Duc. The really historical parts of the walls of the old City of the Popes will not be touched, says *The Times's* correspondent, and it is unlikely that visitors will discover any change in the appearance of the city.

PORTRAIT-BUSTS OF MEMBERS OF THE INSTITUTE OF FRANCE. — It has been customary for the Institute of France to order a bust of each deceased member placed in the hall of the Institute. Recent criticism has led to a proposal to have such busts made when members are elected instead of waiting until their death. Very often the sculptor intrusted with such a commission never saw the savant whom he had to immortalize; and so having nothing but descriptions and, possibly, a few photographs to work from, he produced a bust that had but slight resemblance to the personage whose name it bore. French critics have also pointed out that the men elected to the Academy take their seats at the very time of life when their fame is at its height, and that this is the period when they should be represented, and not at the close of life. It is pointed out that should the modesty of the "immortals" object to the new order of things, their busts can be made when they are elected, but not put in place until after their death. — *Exchange.*

UTILIZING RUBBER SCRAP. — "The utilization of rubber scrap," says the *Electrical Review*, "is of very great importance, for anything that can be added to new rubber to decrease its cost and increase supplies must be welcome, providing that the compound is serviceable. The scraps are sorted according to their composition, and then cleaned by boiling, which removes dirt, absorbed any adhering acids, and free sulphur; but attempts to desulphurize vulcanized rubber have not been successful yet. The waste is ground between rollers and reduced to powder in emery-grinders with automatic feeding, and in many cases the resultant material can be added at once to the new rubber mixture; but generally it is treated chemically by being boiled in a caustic-soda solution or sulphuric or hydrochloric acid, and then steaming for about twenty-four hours at a pressure of four atmospheres. In another method, the ground scraps are steamed with soda-lye under pressure, thoroughly washed twice to remove the lye, and then dried in vacuum. Then they are mixed between cold rollers with from 5 to 10 per cent of benzol or mineral oil and steamed for several hours, at the same pressure as above. After either of these processes, the product is rolled into plates and then added to the rubber dough."

THE FLORENTINE DUOMO AND THE VERSAILLES PALACE. — The decree of the Florentine Republic, which in the thirteenth century ordered the construction of Santa Maria del Fiore, could not be surpassed by any edict of ancient Rome. It says: "Whereas the chief aim of a people of great origin being to act in a way that, from its outward works, every one should recognize both its wise and magnanimous manner of proceeding, we order Arnolfo, chief architect of our city, to make a model or design for the complete rebuilding of Santa Reparata with the greatest possible magnificence that the human mind is capable of conceiving, since it has been decreed in council, both public and private, by the most able men of this city, that nothing should be undertaken for the community which did not correspond entirely to the ideas of its most enlightened citizens united together to decide on such subjects." Contrast this with the pride and fear of Louis XIV — fear of living in view of the sepulchre of his race — which led to the erection of the Palace of Versailles, and we have the direct measure of the difference between the nobility of a religious people, whose imaginations are exalted by art, and the meanness of a ruler who makes art the mere instrument of his self-glory. The relative magnanimity of the two is nowhere more strongly shown than in the disregard of expense actuating each. The king forced a powerful and wealthy nation to the brink of ruin to gratify his selfishness, for the palace has been said to have cost from twelve to forty millions sterling; the republic of Florence contributed their money to erect religious edifices with a proud alacrity which would astonish modern economists. In 1334 they commenced building the present campanile, passing a decree that it should be built so as to exceed in magnificence, height and excellence of workmanship whatever in that kind had been achieved by the Greeks and Romans in the time of their utmost power and greatness. The first stone was laid accordingly with great pomp on July 18 following, and the work prosecuted with vigor and with such costliness and utter disregard of expense that a citizen of Verona, looking on, exclaimed that the republic was taxing her strength too far, that the united resources of two great monarchs would be insufficent to complete it — a criticism which the Signoria resented by confining him for two months in prison, and afterwards conducting him through the public treasury, to teach him that the Florentines could build their whole city of marble, and not one poor steeple only, were they so inclined. This "one poor steeple" is the most beautiful specimen of tower architecture the world has to show, costing at the rate of about sixty pounds per superficial foot, making an entire expenditure of five millions old currency, which, by taking the present value of wheat and comparing it with the price of the fourteenth century, would augment its cost fivefold. — *The Architect.*

THE AMERICAN ARCHITECT AND BUILDING NEWS

VOL. LXXVI SATURDAY, APRIL 5, 1902 No. 1371

CONTENTS

SUMMARY: —
The Form of this Week's Issue in the International Edition. — Legislating for the Ventilation of New York School-houses. — The Reforestation Movement in New Hampshire. — The Great Stairway at Copan, Honduras. — Accidents caused by the Splitting of Stone through the Rusting of inserted Iron. 1
NOTES ON IRON AND STEEL CONSTRUCTION. — VI. 3
LA HUNAUDAYE, BRITTANY. 6
ILLUSTRATIONS: —
Tentative Sketches for "Wheatleigh": House of H. H. Cook, Esq., Lenox, Mass. — Preliminary Study for the Same. — Terra-cotta Details from the Same. — Statue of "Helvetia" in the Entrance-hall of the Union Bank Building, Zurich, Switzerland.
The Château de Clambeau, Nièvre, France.
Additional: "Wheatleigh": House of H. H. Cook, Esq., Lenox, Mass.: —The Entrance-front; Main Entrance; A Gate-post; Rear Entrance-arcade; Side View; Lawn Front; Garden Front. — Harvard Union, H. U., Cambridge, Mass.: — The rear View; East End of Living-room; West End of Living-room. — Details of Interior Treatment of the House of Colonel Guffey, Pittsburgh, Pa.: Six Plates. — House of Giraud Foster, Esq., Lenox, Mass.: — The South Front; The Vestibule; The Main Hall; Mantlepiece in the Main Hall; The Main Staircase; The Palm-house; The Palm-house Entrance; The Dining-room; The Den; The Living-room; A Fireplace in the Living-room; A Corner in the Parlor; Fireplace End of the Parlor. — The Field Memorial Library, Conway, Mass.: — The Main Front; Entrance Portico; The Delivery-room. — "Elm Court": House of W. D. Sloane, Esq., Lenox, Mass. — The Lawn Front; The New Front; The Entrance Front; Side Entrance. — Statues from the Maximilian Tomb, Innspruck, Tyrol, Austria: Four Plates. — Statues from the Maximilian Tomb, Innspruck: Seven Plates. — A Monument to the Memory of M. Edouard Remy, Louvain, Belgium. — Views at the Pan-American Exposition, Buffalo, N. Y.: — The Electric Tower; "Gen. W. T. Sherman": Model of Equestrian Statue for New York, N. Y.; "The Challenge"; The Triumphal Causeway: The "Fountain of Man"; The "Fountain of Nature"; The "Struggle for Existence": a Fountain; Termes and Electric Candelabra in the Sunken Garden; A Pavilion of the Manufactures Building; Terrace of the Propylæa; "The Chariot Race"; Base of the "Fountain of Nature." — Doorways at Beauvais and Provins, France. — Transept Door, Cathedral of Coutances, Manche, France, — Church Doorways, Le-Mesnil-St.-Denis, France. — Church at Berzy-le-Sec, near Soissons; — Church at Braine, France. — Church at Frouville, France; — Abbaye de la Luzerne, St. Pierre-Langers, Manche, France. — Church at Vailly, Aisne, France; — Church at Vasseny, near Soissons, France. — Candelabra, 149 Broadway and 20 Broad St., New York, N. Y. — "The Medicine Man," Paris Exposition of 1900; — Colonnade of the Louvre and Fremiet's Statue of "Velasquez," Paris, France. — The Fountain of St. Sulpice, Paris, France; — The Chapel of the Sorbonne, Paris, France. 6
NOTES AND CLIPPINGS. 8

SUBSCRIBERS to the International Edition will receive with this week's issue the full quota of "additional" illustrations that, under our former system of publication, would be sent them distributed between this and the next twelve issues of the *American Architect*; thereafter and until the first issue for July the mail will bring them each week, in place of the familiar blue-covered International copy, the straw-colored copy of the Regular Edition with its quota of text and illustrations. So on July first they will find they have received the exact amount of text and illustrations that belong to a quarterly volume, but that it has reached them in an unusual combination and order. The change now made is an experimental one and can be continued or abandoned according as the subscribers express to us their approval or disapproval of it. For our own part, we are not in a position to know whether the change is likely to be a relief or an added burden; this number has certainly been burdensome, since we have had to prepare and manufacture in thirteen weeks the amount of illustrative material that hitherto has been evenly distributed over twenty-six weeks. But as the object of the change is not to procure relief for ourselves, but to render better service to our subscribers, we give to our own opinions and feelings a quite secondary place in the consideration of the problem. The illustrations contained in this issue afford excellent evidence as to the manner in which the change is beneficial to the subscriber: it seems to us that it is unquestionably rendering better service to place in the hands of a subscriber at one and the same time all of the plates illustrating a given subject — "Wheatleigh," for example — than to dole them out to him two or three at a time during a succession of weekly issues more or less interrupted by the interpolation of dissociated material. One factor in the situation prejudicially affects the adoption of this new method of issuing the International illustrations in quarterly, in place of weekly, installments: we have been unable, as yet, to induce the postal authorities to allow us to send this quarterly issue through the mail prepared in such a way as to ensure it against damage in transit and place it in the subscribers' hands in a form that the quality and cost of the product requires and deserves. We have, however, prepared suitable heavy portfolio covers which can be mailed to any subscriber on the receipt of fifteen cents in stamps.

A BILL is pending before the New York Legislature to establish rules for the construction, ventilation and sanitation of school-houses and other public buildings, similar to those which have for several years been enforced in Massachusetts, to the very great advantage of school-children and other persons. The proposed New York law is very moderate in its demands in the matter of ventilation, requiring only fifteen cubic feet of fresh air per minute for each pupil in school-rooms, which is just half what Massachusetts children are by law entitled to, and, thanks to the efficiency of their good friends, the State inspectors, generally receive; but it would, perhaps, be difficult to enforce a more radical provision in New York at present. In other respects, the proposed law follows quite closely the statute of Massachusetts, and experience in the latter State has shown so clearly the great advantage to the public, and particularly to school-children, of such provisions that it can hardly be doubted that New York will adopt them. Architects of experience will remember that the Massachusetts law was passed with much difficulty. Nearly all "practical" persons ridiculed the idea of applying "theoretical" ventilation to school-houses, at least outside the great cities. They had learned to spell in school-houses heated by airtight stoves, or, in more advanced communities, by furnaces, which drew the air from the floor of the school-rooms, warmed it up, and sent it back into the rooms, in either case the same air, except so far as leakage around the windows, and transpiration through the walls might affect it, being served up through the entire winter. In extreme cases, a "ventilator" was provided, in the shape of a hole in the school-room ceiling, through which the hottest of the air escaped into the garret. In a community where such ventilation as this was the universal rule, and was perfectly satisfactory to all except a small group of "cranky" theorists, the task of introducing forced ventilation by law seemed hopeless, and there is good reason for suspecting that many of the legislators who voted for the passage of the bill never imagined that it would be enforced. For a time, in fact, its provisions were laughed at, but the inspectors quietly and perseveringly made their rounds, and, as one offender after another received a sharp admonition from the State officials, it began to dawn upon people that the new law was to be enforced. Even then, for many months it was systematically evaded. Multitudes of ventilation-fans, put in at the order of the Chief of the State Police, were operated only while the inspectors were looking on, and stopped as soon as their backs were turned; but even this reluctant concession showed people something of the difference between foul and fresh air, and the parents of the school-children soon began to interest themselves in seeing whether the law was complied with. A complaint from any one of these brought the State inspectors to the spot again, armed with their anemometers, and after a few school-houses had been ordered closed for non-compliance with the law, school-committees began grumblingly to prepare for obedience. All this was not very long ago, yet, since then, a great change has taken place. No architect in Massachusetts thinks now of planning a school-house without calculating the sizes of his ventilation-ducts, and studying the best position for them; and, if he neglects to do this, the State inspectors, who must approve the plans before they can be carried into execution, give him the necessary directions. When the school-house is built, if it is large enough to require steam-heating and fan-ventilation, a licensed engineer is engaged as a matter of course, not to stop the fan, and shut off the fresh air, as soon

Entered at the Post-Office at Boston as second-class matter

as the inspectors are out of sight, but to keep the ventilating system in constant and efficient operation; and scholars, teachers and parents in Massachusetts, who now thoroughly appreciate the difference between good and bad air, would no more think of going back to the old system than they would of discarding their text-books of arithmetic, algebra, geography, Latin and French, and devoting their attention to the "New England Primer" and "Nature Display'd."

NEW HAMPSHIRE possesses a very energetic Society for the Protection of Forests, as well as some owners of forest land who are inspired with modern ideas in regard to their property. The latter have, within a few years, been quietly experimenting in forest planting, and the results are in the highest degree encouraging. Naturally, planting is done mostly with white pine, as this timber is easily grown in New Hampshire, and, owing to the exhaustion of the supply, brings a high price; and, as has been almost invariably the case where scientific forestry has been tried in this country, the rapidity of growth of the trees properly set out and cared for has surprised people accustomed only to the slow and uncertain increase of neglected forests. In one case, where young pines, five years old, were set out on a sandy hill twelve years ago, many of the trees are now seven inches in diameter, at two feet from the ground, and the thinnings alone are of considerable value. In another case, where a pine forest was carefully cut twelve years ago, so as to save the saplings, the latter are now beginning to furnish salable timber, ten years sooner than would have been the case under the usual management. While the more enlightened land-owners are carrying on practical experiments, the Society, which includes merchants and professional men, as well as forest-owners, is earnestly advocating a measure for the exemption from taxation of plantations of young pine, and pine forests scientifically managed, and it is hoped that it may be passed at the approaching session of the Legislature. If adopted, it will be, we think, the first statute of the kind in our timber-growing States, and its effect will be watched with great interest. So far as we can tell from the example of Germany, the result of such a law in New Hampshire should be to transform it rapidly from a rather declining community, with its principal wealth fast being stripped from it by railways and lumber corporations, into a prosperous and animated one, busily employed in producing and converting into valuable goods the unrivalled timber which Nature has given only to four or five of the States on the Atlantic slope, at the same time that it is storing up wealth, happiness and comfort for future generations. We have been told for the last fifty years that the decline of population in Maine, New Hampshire and Vermont was due to the fact that their inhabitants depended upon farming, and that the farmers in the Mississippi Valley could undersell them. The people of Vermont have had the good sense, instead of trying to compete with the Kansas farmers in raising wheat, to dig up, cut and send to market the beautiful marbles of which their State possesses an inexhaustible variety, and are beginning to be prosperous once more; and Maine, New Hampshire and Massachusetts have, in their soil and climate, unlimited resources for the perennial production of a timber which will grow in perfection nowhere else, except in portions of Pennsylvania and the Lake regions, for which there is a demand absolutely without limit, owing to its superiority to any other timber ever discovered, at prices three times as high as those which brought enormous fortunes to the owners of the pine lands of the last generation. To make available, however, the wealth which lies dormant in the soil of the white-pine States, patience and self-denial are necessary for a few years; and, as individuals without resources are unable to practise self-denial of this sort, it is indispensable that the State should help, if not by doing something to support the forest-planter and his family until his trees begin to be marketable, at least by relieving him of the burden of taxation. It must be remembered that, while a farmer can easily deduct a reasonable annual tax from the price of his yearly crops, the forest-planter has absolutely no resource, until his trees are marketable, for meeting taxation, except by taking from the scanty savings which he has been able to lay by in some other employment. No one can reasonably be expected to assume this burden, in addition to the heavy outlay required for starting a productive forest, and, until some distinction is made by the State authority, in which the difference between forest planting and potato raising is recognized, no general interest in forestry, on the part of people who own forest lands, can be hoped for.

THE Peabody Museum of American Archæology of Harvard University, aided by contributed funds, recently fitted out an expedition to Copan, in Honduras, under the direction of Mr. George P. Gordon, which has done an excellent preliminary work in clearing and recording the hieroglyphic inscriptions on what is known as the Great Stairway, which leads from the plain up what seems to be an artificial pyramid, once, probably, crowned with a temple. The faces of the steps of the stairway were covered with hieroglyphic inscriptions, and the balustrade was sculptured with symbolical figures, while at least five statues stood at regular intervals on the steps and landings. When the Harvard expedition reached the spot, the ruins were buried in débris, and it has taken four years of labor to clear them. The whole stairway proves to have consisted of some seventy steps, each twenty-five feet long, the lower step being wider than the others. The lower step is not ornamented, but all the others are decorated on the face with hieroglyphics, in panels, interrupted occasionally by sculptured figures. All the figures seem to be in some way symbolic. Some of them hold in their hands a fish, which is very common in Central American sculpture, and seems to have some sacred significance; others are connected in some way with serpents, the rattlesnake being often shown; and serpents, alternating with figures of birds, form the decoration of the richly-carved balustrade. Of the statues which stood on the stairway many fragments remain, showing that they must have represented sitting figures, generally crowned with enormous head-dresses of plumes, sometimes mingled with serpents, and wearing, in at least one case, a breastplate representing a death's head, very much as Athena wore the head of Medusa. At the foot of the staircase are the remains of what is supposed to be an altar, having the form of some enormous animal, but now headless, and otherwise defaced. Some fragments of the sculpture show traces of colored stucco over the stone, and Mr. Gordon is inclined to believe that the whole of the staircase, with its balustrades, was once covered with stucco in this way. Of the temple to which the staircase led, nothing now remains in place, but many fragments of it are mingled with those of the staircase. In excavating to determine the form of the foundations of the temple, and the terraces which were connected with it, Mr. Gordon made the very interesting discovery that they rested on the remains of still older buildings, and, in some places, the traces of several distinct layers of débris were found, indicating that, as at Troy, the sacred Acropolis of Copan had been several times built over, in successive ages, the earliest structures dating, apparently, from an antiquity perhaps more remote than any yet known to archæology.

PEOPLE who expect to go to London to witness the coronation of King Edward the Seventh next June will do well to avoid standing on the balconies of London houses to see the coronation procession, or any similar sight. A few days ago, some people were standing on the balcony of a house on Pembroke Square, in London, when the whole affair suddenly broke down, dropping the people on it into the area below. It appeared, on examination, that the iron supports of the balcony were fixed in a stone string-course which ran across the front of the house, and this string-course had split off for its whole length. It is probable that the rusting of the iron, where it was set into the string-course, had begun to split the stone, and a small additional strain was sufficient to cause its separation. There are numberless examples in this country of such splitting of stone, particularly of the hardest kinds, by the rusting of fence-posts, or other pieces of ironwork, fixed in it. The lead and sulphur generally used to secure the iron in its place are said to increase the disposition to rust, this being particularly the case with sulphur; and after some years, the stone around the point of insertion of the iron begins to split in the direction of least resistance, which is usually that of the length of the stone. Occasionally, the granite base of a long cemetery railing, or yard-fence, may be seen split from end to end in this way, and architects expect, as a matter of course, to find cracks in stonework in which iron has been set for any considerable time. Quite recently, some architects have discarded lead and sulphur for setting iron in stone, and have used clear Portland cement in place of them. Theoretically, this should diminish the tendency to rust, and an examination of ironwork so set might furnish valuable information in regard to the all-important question of preserving iron in contact with masonry from corrosion.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — VI.

THE rivets used in structural work are of a low-grade steel, and the usual sizes range from $\frac{5}{8}$ inch to 1 inch in diameter, $\frac{3}{4}$-inch diameter rivets being the most used; $\frac{7}{8}$-inch and 1-inch diameter rivets are used where the plates and rolled shapes are heavy, or where the grip of the rivet — *i. e.*, the distance from head to head — is great; $\frac{5}{8}$-inch rivets are only for light work, principally for light trusses, stair and other architectural ironwork.

A joint will fail in two ways, *i. e.*, by the shear of the rivets or by the crippling of the plate around the rivet-holes. The rivets never fail by bending, and their transverse strength is never considered. Rivets may be in either single or double shear, and the bearing of the plate may be either ordinary or web bearing. Single shear is where the rivet tends to shear through one section only, as along the line *a a* in Figure 35, while double shear is where the rivet tends to shear across two sections, as shown along the lines *b b* in the same figure. Web-bearing exists in a plate held between two side plates so that the bearing around the rivet-hole is in a direct line — *i. e.*, there is no side pull upon the middle plate. The plates marked *c* and *d* in Figure 35 are in ordinary bearing, while the plate marked *e* is in web-bearing. The allowable unit shearing-value for steel rivets in building-construction is 7,500 pounds, while the allowable unit bearing-value is 15,000 pounds; higher values than these can be used when the material or workmanship is of exceptional quality, or economy demands it. The single shearing-value of any rivet is equal to the area of the rivet multiplied by the allowable unit shearing-stress, while the double shearing-value of any rivet is twice the single shear. The ordinary bearing-value of a plate is usually taken as the diameter of the rivet multiplied by the thickness of the plate multiplied by the allowable unit bearing-value. Where the plate is in web-bearing it is customary to take one and one-half times the ordinary bearing as the allowable bearing-value. When several rolled-steel shapes are held together by rivets which are driven when hot, there is a tendency of the rivets to clamp the plates or grip them by the contraction of the rivets on cooling. While experiments show that the rivets grip the plates to a certain extent and prevent them from sliding one past the other, they have also proved that the amount of this gripping or clamping tendency is indeterminate; it is, therefore, not considered in the design of structural work.

1	.7854	7,854	15,708	5,000	6,250	7,500	8,750	10,000	11,250	12,500	13,750

NOTE. — All values between the heavy lines are greater than the single shear of the rivets and less than the double shear; so that, if the rivet is in single shear, that value is used, while, if the rivet is in double shear, the bearing-value of the plate is taken in designing the connection.

Since a riveted joint or connection may fail, either by the shearing of the rivet or the crippling of the plate, it is necessary to analyze both values, and to determine where the failure is likely to occur, for the strength of the joint or connection depends upon the strength of its weakest part.

In order that the resistance of rivets or the bearing-value of the plates may readily be determined, a table such as the foregoing is often prepared; this table gives the shearing and bearing values for rivets of different diameters, and for plates of different thicknesses when different shearing and bearing values are considered. It will be found convenient for reference in all future calculations.

In structural work there are certain practical considerations

[1] Continued from No. 1368, page 85.

besides mere strength, that determine the spacing of rivets. These rules are practically standard.

In order that the rivet-hole may not pull out at the end of a plate, it is usual to make the distance from the centre of the rivet-hole to the edge of the plate not less than one and one-half times the diameter of the rivet, nor greater than eight times the thickness of the plate, while the minimum distance from the centre of a rivet-hole to the side edge of a plate should be one-half of the diameter of the rivet, plus one-half the thickness of the plate, plus $\frac{1}{8}$ inch. Rivets should never be placed closer together than three times the diameter, and the pitch should not exceed sixteen times the thickness of the thinnest outside plate, provided such a distance does not exceed 6 inches, though in plate-girder work it is sometimes found advisable to space rivets as far apart as 9 inches. Where rolled-plates are in compression, the maximum pitch in the direction of the stress should never exceed sixteen times the thickness of the plate, nor thirty-two times the thickness of the plate in a direction at right angles with the line of stress. Exception to this rule exists in cover plates of deep chords and end posts in a truss, where the pitch may be as great as forty times the thickness of the plate. At the end of compression-members the pitch should not exceed four times the diameter of the rivet for a length equal to twice the width of the member, while the pitch throughout the balance of the length may be made the maximum. The following table gives data regarding rivet-spacing which will be of value in the design of structural members: —

TABLE OF RIVET-SPACING GIVING MAXIMUM AND MINIMUM DISTANCES IN INCHES.

Size of rivet.	Minimum pitch.	Maximum pitch at the ends of columns and compression-members.	Minimum pitch in the flanges of girders.	Distance from edge to centre of rivet-holes.	
				Minimum.	Usual.
$\frac{3}{4}$	$1\frac{1}{2}$	$2\frac{1}{2}$	3	$1\frac{5}{16}$	$1\frac{1}{4}$
$\frac{7}{8}$	$1\frac{3}{4}$	3	3	$1\frac{1}{16}$	$1\frac{3}{8}$
1	2	$3\frac{1}{2}$	$3\frac{1}{2}$	$1\frac{3}{16}$	$1\frac{3}{4}$
$1\frac{1}{8}$	$2\frac{1}{4}$	4	4	$1\frac{1}{2}$	2

It is customary in designing riveted connections that are to be put together in the field to allow 25 per cent greater resistance in the rivets than was employed in the shop-work. This is to allow for defects in workmanship and material, for in the field it is difficult to drive the rivets perfectly, and in extremely cold weather they are likely to be cooled very rapidly and driven at a low heat, the heads, in consequence, being very brittle and the rivets being insufficiently upset to fill the holes. In all rivet-work put together in the shop the holes are punched $\frac{1}{16}$ inch larger than the rivet. They should be made true to a templet, and no drift-pins should be used to bring the work together. It is advisable to drill all of the rivet-holes for field-connections, and these holes should be drilled while the pieces are securely clamped or bolted in correct juxtaposition. If they are punched they should be reamed so that excessive drifting in the field will be avoided. Rivets may be driven in shop or field; they may be countersunk on one or both sides or flattened. To designate upon a drawing in what manner the rivets should be driven it is customary to use Osborne's code. This code is shown in Figure 36 and is easily remembered after careful observation.

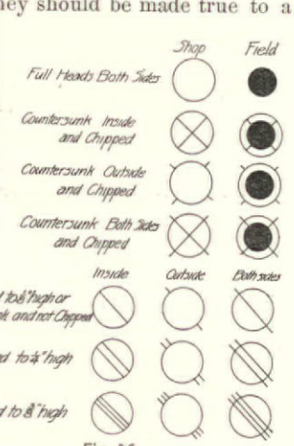

Fig. 36.

It is necessary in designing plate girders to have sufficient rivets through the vertical leg of the flange angles, in order to transmit the stress from the web to the flanges. Theoretically, the pitch of the rivets through the vertical leg of the flange angles would vary from the abutments to the centre, the rivets being placed very closely together at the abutment and extremely far apart towards the centre of the span. In order to facilitate work in the shop it is usual to provide only two or, at the most, three different pitches throughout the length of a girder. Where the girder is divided by the stiffeners into panels and the length of the panel is equal to the depth of the girder, the pitch of the rivets in the vertical leg of the flange angles between any two stiffeners may be determined by dividing the vertical shear at the stiffener nearest the abutment by the allowable value for one rivet, and by dividing this result,

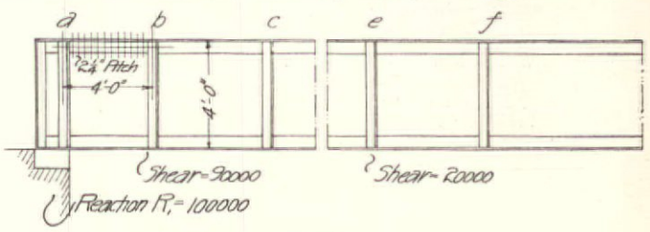

Fig. 37.

which is the number of rivets required between the two stiffeners, into the distance in inches between the stiffeners or the depth of the girder. For instance, it is desirable in Figure 37 to obtain the rivet-spacing between the points *a* and *b*. These points are 4 feet apart, which is the depth of the girder; the reaction R_1 equals 100,000 pounds. According to the above, therefore, the number of rivets required between *a* and *b* is equal to 100,000 pounds divided by the allowable resistance for one rivet. Supposing that the rivets are $\frac{3}{4}$ inch in diameter, the shearing and bearing values may be found from the foregoing table. The allowable unit shear is 6,000 pounds and the unit bearing-value is 12,000 pounds, so that a $\frac{3}{4}$-inch rivet through a $\frac{5}{16}$-inch web-plate and $\frac{3}{8}$-inch flange angles will have an allowable value equal to the web-bearing of a $\frac{5}{16}$-inch plate, or one and one-half times 2,810, which gives 4.215; then $100{,}000 \div 4{,}215 = 23.7$, or 24 rivets; dividing 24 into 48 inches, the distance between *a* and *b*, the pitch of the rivets, is ascertained to be 2 inches; this is somewhat below the minimum pitch, which, as previously stated, should never be less than three times the diameter of the rivet; it would, therefore, be good practice to pitch the rivets between *a* and *b* as near as possible to $2\frac{1}{4}$ inches.

Again, assume that it is desired to determine the pitch of the rivets between *b* and *c*. The shear at *b* on the girder is found to be 90,000 pounds; therefore 90,000 pounds $\div$ 4,215 = 21.3, or 22 rivets; consequently, the pitch between *b* and *c* is equal to $48 \div 22 = 2.18$; this pitch is theoretical, and would probably be made the minimum pitch. At a panel nearer the centre of this girder, as at *e*, the shear is 20,000 pounds; then the number of rivets required between *e* and *f* would equal $20{,}000 \div 4{,}215$, or 4.7, say 5 rivets; $48 \div 5 = 9.6$ inches, the theoretical pitch between *e* and *f*; this greatly exceeds the allowable pitch for rivets in a compression-member. Since the upper flange is practically a compression-member, the rivets must be spaced not farther apart than 6 inches; the rivets throughout the girder then would probably be spaced through the first two panels $2\frac{1}{4}$ inches; through the next two, 3 inches; the next two, 4 inches, and throughout the remaining portion of the girder, 6 inches.

A somewhat similar method, though more accurate, for proportioning the rivets through the flange angles and web-plate of a girder is to determine the increment of stress transmitted from the web-plate to the flange angles at each point. The maximum increment of the horizontal flange stress at any point in the length of a plate-girder is equal to the shear at that point divided by the depth of the girder in inches; consequently, if the increment for each inch in length may be determined, the pitch of the rivets may readily be ascertained by dividing

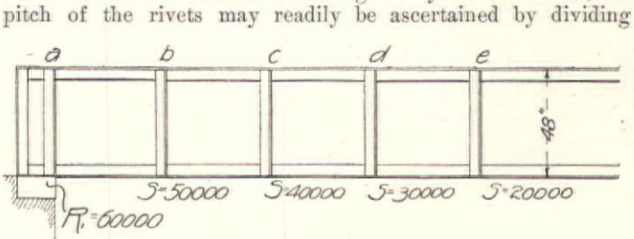

Fig. 38.

the allowable resistance of one rivet by the increment. Assume that it is desired to proportion the rivets throughout the vertical leg of the flange angles in the girder shown in Figure 38 and also assume that the allowable resistance of one rivet is

4,000 pounds; the reaction R_1 equals 60,000 pounds, and the increment of stress at a, b, c, etc., is as follows: —

Increment a = shear a = 60,000 pounds ÷ 48 = 1,250
Increment b = shear b = 50,000 pounds ÷ 48 = 1,042
Increment c = shear c = 40,000 pounds ÷ 48 = 833
Increment d = shear d = 30,000 pounds ÷ 48 = 625
Increment e = shear f = 20,000 pounds ÷ 48 = 417

Since the allowable resistance of a rivet equals 4,000, then the pitch of the rivets between the several points is as follows: —

Between a and b = 4,000 ÷ 1,250 = 3.2
Between b and c = 4,000 ÷ 1,042 = 3.8
Between c and d = 4,000 ÷ 833 = 4.8
Between d and e = 4,000 ÷ 625 = 6.4
Between e and f = 4,000 ÷ 417 = 9.6

From the above tabulation, in practice the girder would be designed with rivets pitched 3 inches apart in the first panel, 4 inches apart in the next, while between c and d would probably have the rivets spaced 5 inches apart, the rivets throughout the remaining length of the girder being spaced the maximum distance, namely, 6 inches.

The rivet-spacing in the vertical leg of the flange angles may be determined by another method, which consists in calculating the bending-moment at the several panel points, and then determining the flange stress at these points. When the flange stress has been determined at any point, the number of rivets between that point and the abutment may be determined by dividing the flange stress by the allowable resistance of one rivet.

Example. — The girder shown in Figure 39 is loaded with a

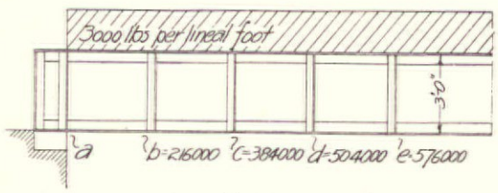

Fig. 39.

uniformly distributed load of 3,000 pounds per lineal foot, and the bending-moment at a, b, c, d and e is as follows: —

a = 0 foot-pounds.
b = 216,000 foot-pounds.
c = 384,000 foot-pounds.
d = 504,000 foot-pounds.
e = 576,000 foot-pounds.

The flange stress at the several points is, therefore, as follows: —

a = 0 ÷ 3 = 0
b = 216,000 ÷ 3 = 72,000
c = 384,000 ÷ 3 = 128,000
d = 504,000 ÷ 3 = 168,000
e = 576,000 ÷ 3 = 192,000

From the above data the number of rivets between b and a may be found by dividing the flange stress by the allowable resistance of one rivet, likewise the number of rivets between c and a may be found by dividing the flange stress at c by the allowable value for one rivet; by deducting from the number of rivets required between c and a, the number of rivets necessary between b and a, the rivets between c and b may readily be found. Likewise the rivets between d and c may be obtained by deducting from the number of rivets required between d and a the number of rivets necessary between c and a. Having the number of rivets between each of the panel points, the pitch may readily be found by dividing the number of rivets into the distance between the centres of the stiffeners. If in the girder in question the allowable resistance of one rivet is 4,000 pounds, the number of rivets between the several points may be obtained by the following calculation: —

Number of rivets, a to b = 72,000 ÷ 4,000 = 18
Number of rivets, a to c = 128,000 ÷ 4,000 = 32
Number of rivets, a to d = 168,000 ÷ 4,000 = 42
Number of rivets, a to e = 192,000 ÷ 4,000 = 48

Then

Number of rivets, a to b = 18
Number of rivets, b to c = 32 — 18 = 14
Number of rivets, c to d = 42 — 32 = 10
Number of rivets, d to e = 48 — 42 = 6

and,

Pitch of rivets, a to b = 48 ÷ 18 = 2.66 inches.
Pitch of rivets, b to c = 48 ÷ 14 = 3.43 inches.
Pitch of rivets, c to d = 48 ÷ 10 = 4.8 inches.
Pitch of rivets, d to e = 48 ÷ 6 = 8 inches.

Besides these several analytical methods the rivet-spacing in the flange-angles may readily be determined graphically by the

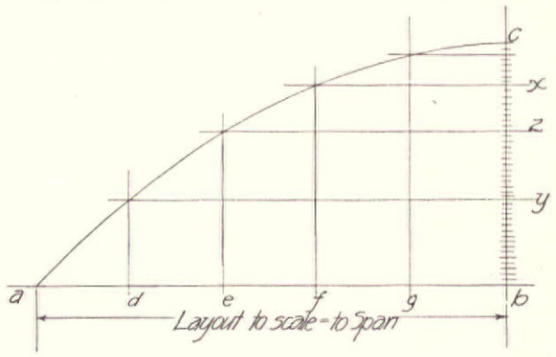

Fig. 40.

use of the parabolic curve, as explained in connection with the shortening of the flange-plates; that is, of course, where the girder is uniformly loaded. Figure 40 shows parabolic curve a-c; the line $c\,b$ is laid off into as many equal parts as there are rivets required between the centre of the girder and the abutments. The number of rivets may be determined by any of the above-described methods, *i. e.*, by calculating the flange stress at the centre of the girder by means of the formula $\frac{W\,L}{D\,8}$, in which W equals the uniform load upon the girder, L the length of the girder in feet, and D the depth of the girder in feet. The distance $a\,b$ in Figure 40 is laid off to scale equal to one-half of the span of the girder, and at the points where it is desired to change the pitch of the rivets, as at d, e, f, g, etc. (these points being usually located at the centre line of the stiffeners), extend upward the ordinates as shown until they intersect the parabola; from these points of intersection describe the horizontal lines, and by counting the number of divisions between these horizontal lines, the number of rivets between the several panel points, or points at which it is desired to change the pitch, may be determined. For instance, in the figure the number of divisions between b and y denotes the number of rivets required between a and d, while the number of rivets between d and e, and e and f, may be determined by counting the number of division between $y\,z$, and $z\,x$ respectively. By making a general diagrammatic scale having for its principle this method, a convenient means of obtaining the number of rivets required through the vertical leg of the flange-angles may be obtained.

In spacing the rivets through the horizontal leg of the flange angles — that is, through the cover-plates — it is good practice to place sufficient rivets in the end of each cover-plate, pitched at a distance not farther apart than four times the diameter of the rivet in order to equal in resistance the net sectional area of the plate; the rivets throughout the remaining length of the plate being spaced at the maximum pitch. For instance, in a $12'' \times \frac{1}{2}''$ plate there are two $\frac{7}{8}$-inch rivet-holes in a straight line across; in consequence, the net area of the plate is practically 5 inches; if the allowable unit-stress of the material is 15,000 pounds, the net strength of the plate is 75,000 pounds.

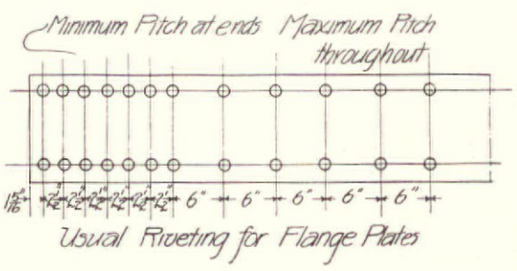

Fig. 41.

Provided the rivets have an allowable resistance of 6,000 pounds, there will be required in the end of the cover-plate 75,000 ÷ 6,000, or 12.5 rivets, or 13. As this is an odd number, and because the rivets are spaced symmetrically along

each edge of the cover-plate, 14 rivets will be required in the end. These will be spaced as shown in Figure 41; the remaining rivets throughout the length of the cover-plate being 6 inches.

It is difficult to obtain rolled angles and plates longer than 70 or 80 feet — *i. e.*, when they are of any size; it is, therefore, often necessary to splice both the cover-plates and flange-angles. It is not necessary that all splices in the upper chord be heavy, because they are only needed to keep the plates and angles in alignment, since this portion of the girder is in compression, but where it is necessary to provide splices in the lower flange of the girder, care should be taken in proportioning the splice to obtain the greatest percentage of strength, and sufficient rivets must be placed in each side of the abutting joint to equal the net resistance of the rolled section. Wherever possible these splices should be placed as near as possible to the abutments, because at such points the bending-moment is less. Where the flange-angles are spliced, the splices should not occur opposite each other — *i. e.*, the joints should be broken.

The application of the several principles and rules set forth in the foregoing will be demonstrated in a future article, which will show the general design and several details of construction for plate-girders, and their connections to structural-steel columns such as would commonly be used in building-construction.

M. M. Sloan.

[To be continued.]

LA HUNAUDAYE, BRITTANY.

THERE are many crumbling old ruins in France and not a few in Brittany, but none more lonely or forgotten than that of the castle of La Hunaudaye, buried in a forest that looks as if it had not changed in the last thousand years.

The forest of La Hunaudaye, or forest of Laumor, as it was also called, was, in the Middle Ages, a rendezvous for all the brigands of the country. They used to attack travellers who passed that way and were not sufficiently guarded. Among those who suffered was the Bishop of Saint-Brieux, who, one day in the fourteenth century, was attacked by these ruffians while crossing the forest and only liberated on his promising to pay a heavy ransom, losing at the same time his horses and all his baggage. The trees of this forest were principally oak, beech and chestnut — that truly Breton tree, which also furnished a thick undergrowth in which the wild boar was often found. Badgers and squirrels are at the present time its most dangerous inhabitants, although, if the winter is severe, it is not uncommon to see a pack of hungry wolves come stealing out in quest of prey which they failed to find in its dark retreats.

It was not only on account of the atrocities committed by its robbers that the forest of La Hunaudaye was famous; far greater was the terror caused to all the Breton peasants by its owner, the noble and puissant Seigneur Tournemine de la Hunaudaye, whose magnificent castle, built in the years 1214–1220, was noted in the annals of Breton chivalry. Its architect, says Freminville, wished to unite elegance with strength. The castle, standing in the centre of the forest, was in shape heptagonal, flanked by seven towers a good deal higher than the main building and surmounted by turrets. In addition to these, two other towers protected the entrance, one on each side, the whole surrounded by a double moat; the walls were about forty feet in height and of great thickness. Both walls and towers were surrounded by outstanding parapets so that, in case of attack, boiling oil and melted pitch might be poured on the besiegers. In the centre of the court was a deep well, where the inhabitants could always get their supply of water in times of war.

But none of this original splendor longer exists, for during the French Revolution violent hands were laid on the castle, as on so many others, and it suffered the same fate; its owner was forced, by order of the directors of the district of Lamballe, a town some fifteen miles distant, to set fire to his own castle, lest it should fall into the power of the Royalist army. It was then the property of Mme. de Talhouet, a descendant of the family of Tournemine. It is said the fire lasted eighteen days before it burned itself out.

The prison-tower in particular attracts the attention of the visitor of the present day, its walls being covered with inscriptions or figures carved on the stones by the prisoners who had been detained there. One of the figures is an infant swathed according to the custom of the country; another, a cross and stars. This is the only apartment that still keeps its roof; it was stone-vaulted, and so resisted the fire. The entrance to the prison is easily recognized, as there are triple doors, and in the wall holes or sockets into which the bolts were shot; besides, there are other and deeper holes, where bars of iron could be placed across for greater security. In the centre of the castle stood the chapel, its Gothic windows and carved doors bearing testimony to its pristine beauty. Directly under the chapel is the entrance to a subterranean passage, its secret door having been burned away with all the rest. Should any one be tempted to explore this dismal route he will encounter complete darkness, a cold, damp feeling and a most peculiar noise, caused by a multitude of bats escaping from the unusual sight of a visitor to their abode, for few strangers go to La Hunaudaye, and the peasants rarely go inside the castle at all, much less would they venture into the gloom of its underground mysteries. If you ask why, you would probably get the same answer as did the writer from an aged peasant living on the farm close at hand, who told this tale in Breton-French:

"Some hundred years ago, monsieur," said he, "the castle was owned by Seigneur de Tournemine, an atrociously cruel man, who, in order to get possession of it, killed his father and his elder brother. His wife, who was a good woman, often reproached him with his crime, so he got rid of her in the same way. A few days after he had murdered her, a dreadful storm arose. It was late at night, and the Seigneur was sitting in his room when a loud knock sounded at the door. The sentinels had not observed any one come down the avenue, which, as you see, is over a mile long. However, a tall man, dressed in red, was ushered into the Seigneur's presence. Every one was greatly astonished to find that, although it was raining in torrents outside, his clothes were perfectly dry. 'Who art thou?' said De Tournemine, 'and how dare you come into my castle without a retinue at this hour of night?' 'My retinue is present,' answered the strange visitor. 'Let them appear,' and instantly the three figures of the father, brother and wife became visible. All were ghastly white and wrapped in shrouds, which they opened, and showed the blood pouring from their wounds. Then the cavalier in red said: 'Baron, I have no other guard,' and pointing to the eldest of the three spectres he added, 'There is your father, a holy old man, who was slain by a dagger thrust. There,' turning to the younger, 'is your brother, and there is your wife. You are the murderer of all three, and you know it.' Then the three ghosts laid hold of the Seigneur de Tournemine and he fell dead at their feet. The man in red laughed and all four vanished. During this time the lightning was rending the skies and peal after peal of thunder reverberated in the valleys."

Such is the legend of La Hunaudaye, and the country-folk believe that the castle is still haunted by the mysterious four. — *N. Y. Tribune.*

STATUES FROM THE MAXIMILIAN TOMB, INNSPRUCK, TYROL, AUSTRIA: FOUR PLATES. DRAWN BY A. C. CONRADE.

THE tomb of Maximilian I in the Hofkirche at Innspruck is one of the most remarkable memorials that exist, partly because the tomb does not enclose the remains of the Emperor, who was actually sepulchred at Wiener Neustadt, and partly because, besides the marble tomb itself, adorned with twenty-four bas-reliefs and a bronze effigy of the Emperor kneeling upon the top, the memorial includes a remarkable series of colossal bronze statues, twenty-eight in number, that stand on a stylobate in the intercolumniations of the nave and the transept crossing. These statues are, in the main, the work of Gregory Löffler, that is, the best of them are his work, while others are due to the lesser skill of the brothers Godl. We believe that some of the series were never finished and set in place and are represented by incomplete fragments which still lie in a storeroom, the process of founding and erecting having been interrupted by the wars of the period. Should any one try to assemble a complete statue from this mass of *disjecta membra* a successful result would doubtless be impossible, since, during the wars referred to, much of this bronze material was seized, put into the melting-pot, and converted into arms of such precision as the advance of military science at that time made possible. Nevertheless, the task has been essayed and the figure of "Theodobert, Duke of Burgundy" is the result. It is said that sculptors nowadays have no difficulty in deciding that the sculptor entrusted with the task assembled the wrong fragments and produced a compound result very different from that intended by the original artist. At all events, this meddler was a man of such inferior prowess that he was unable to model a likeness of the Duke, and to disguise his incompetence represented the Duke with the visor of his jousting-helmet lowered.

STATUES FROM THE MAXIMILIAN TOMB, INNSPRUCK: SEVEN PLATES. DRAWN BY MR. C. HOWARD WALKER, ARCHITECT, BOSTON, MASS.

WHEN, a few weeks ago, we came upon, in the *Builder*, Mr. Conrade's interesting drawings of some of the statues in the nave of the Hofkirche, we were at once reminded of the very complete and remarkable water-color drawings exhibited at the Boston Art Club last year by Mr. C. Howard Walker, and we thought it would be interesting, merely as an exhibition of comparative draughtsmanship and artistic skill and feeling, to reproduce those of Mr. Walker's drawings which depicted the same figures drawn by Mr. Conrade. We little imagined that when placed side by side such singular and inexplicable variations and discrepancies would be revealed, and knowing the full history of Mr. Walker's work and his ability, skill and accuracy, we cannot but wonder where Mr. Conrade procured the data on which he founded his drawings. Not upon photographs, evidently, first, because, with the exception of the "King Arthur" and one or two more, the figures have never been allowed to be photographed, and, next, because had they been founded on photographs there would not have existed the discrepancies between them and Mr. Walker's careful work. Sceptres and swords would not appear in hands that Mr. Walker found empty; sword-hilts and daggers would not appear on the wrong side, and the form and position of armorial shields would have been alike in both sets of drawings. A justifiable inference is that Mr. Conrade founded his drawings, made in 1901, on some older published sketches secured at a time when the prohibition against drawing and photographing in the Hofkirche was not so strictly enforced as now.

We will leave to Mr. Walker to tell at another time and in another place the interesting story of how, by address, persistence and a goodly allowance of Yankee shrewdness, he at length secured permission to sketch a few of the statues — which it seems are not so much Crown property as a part of the personalty of the Emperor Francis Joseph — and how by the use of an allowable subterfuge and the speediest of workmanship he managed to expand his "few sketches" into a practically complete record of the entire series. As shown on the walls of the Art Club two years ago, the drawings formed one of the most interesting exhibits that were ever hung there, and formed an impressive monument of industry, perseverance and artistic skill.

NOTES AND CLIPPINGS

WILKINS'S OVERBIG BATTLE-PIECE. — An elephant of a picture is troubling the souls of the Corporation of Hastings-by-the-Sea, England. It is a battle-piece 31 feet 6 inches wide and 17 feet 6 inches high. Painted by Wilkins in 1820, it has never found a wall big enough to contain it, though the Corporation paid $7,500 for it eighty-two years ago. The last suggestion is to offer it to Sir Augustus Webster, the new owner of Battle Abbey, the building erected on the spot where Harold fell to express the gratitude of Duke William for his victory. The moment chosen by Wilkins is the last charge of Duke William, when Harold had fallen by a chance arrow and the Saxons began to flee. — *N. Y. Times.*

THE DOME OF THE PARIS PANTHEON. — The dome of the Panthéon at Paris, beneath which the centenary of Victor Hugo was celebrated, is constructed entirely of stone, and is placed in the centre of a Greek cross. It is supported by four triangular piers strengthened by engaged columns of the Corinthian order. The four piers with the lines of the intermediate arches form externally a large square, each side of which is 74 feet 9 inches. These four piers are pierced above with arched openings, and between the piers with the openings are large arches, the diameter of which is 44 feet 11½ inches, and the height 85 feet 5 inches. Between these arches rise the corbellings, which are gathered in to form the circular plan of the drum. The arches and the corbellings are crowned with a large entablature 13 feet 4 inches high. The upper part of the cornice of the entablature is raised 101 feet above the pavement of the nave. The diameter taken at the frieze is 66 feet. The internal drum which is constructed on this entablature is 55 feet 7½ inches in height to the springing of the internal dome. The interior of this drum is decorated with a continuous stylobate, which is the basement of a colonnade of sixteen Corinthian columns almost isolated from the wall. These columns are 35 feet 2¾ inches in height. Between the columns are sixteen windows; four of which are false, and placed above the four piers of the dome. The colonnade is crowned with an entablature, above which is a large plinth which rises to the springing of the internal dome. The internal dome is 66 feet 8½ inches in diameter at the springing, and is decorated with octagonal caissons or sinkings with a rose in the centre of each. The eye at the top of the dome is 31 feet 3½ inches in diameter. Through this eye is seen the upper part of another or intermediate dome. The external dome is placed on a circular base 108 feet 7½ inches in diameter and square at the bottom. The angles are strengthened by flying-buttresses. Above the corbellings a circular wall is constructed, forming an external continuous stylobate which supports an external colonnade. The external colonnade constructed on the stylobate forms a peristyle round the dome, and is composed of thirty-two isolated columns of the Corinthian order 36 feet 5¾ inches high. This colonnade is divided into four parts by the solid constructions in masonry raised over the four piers. The external colonnade is surmounted with an entablature and balustrade above it. There is an attic constructed above the circular wall of the drum, set back 13 feet 10 inches, and pierced with sixteen windows, twelve of which light the space between the internal dome and the intermediate dome which bears the lantern. This attic is terminated with a cornice with a step or plinth above. The external dome, 77 feet 8¾ inches in diameter, measured on the outside, is constructed with masonry; the height is 45 feet 9½ inches from the top of the attic to the underside of the finishing against which the curve terminates. The outside of the dome is covered with lead, and is equally divided vertically by sixteen projecting ribs. The intermediate dome, built for the purpose of carrying the lantern, was intended to be decorated with subjects by the painter. The form of this dome resembles the small end of an egg; its springing commences at the base of the attic at the point where the internal dome begins to disengage itself. This dome is 50 feet ¾ inch high, 3½ feet and 70 inches in diameter, and is pierced with four great openings at the lower part 37 feet 3 inches high and 30 feet 10½ inches wide at the base. On a circular platform above the summit of the dome are eight piers with arches, which support the finishing against which the external dome terminates. Above this is the lantern of the dome. — *The Architect.*

A DAY'S WORK IN BRITISH BRICKLAYING. — A long letter from Mr. Stewart, the building-manager to the British Westinghouse Electric Co., relating to the number of bricks per day laid by the bricklayers engaged in the erection of the works for that company at Manchester, appeared recently in the *Times*. Replying to the questions, "What is the thickness of the walls? Was mortar or cement used?" Mr. Stewart says that in no instance are the walls less than 19 inches thick, and that in some instances they are 23 inches thick, also that mortar was used, not cement. All the walls are "piers." In the centre of each brick pier is a large "Z" bar steel column. With one exception all the buildings are faced with No. 2 stock-brick. This work may therefore be regarded as closely approximating in character to that performed by the bricklayers employed by the London County Council, but the average number of bricks laid per man per day was 1,400, as against the trade-union standard of 450, or the London County Council average of 330. For "common work" the Westinghouse now averaged 2,250 bricks per man per day. Some explanation of the difference between the speed of British and American work is to be found in the following statement: "Our mortar is made much softer than that commonly used in England, and the bricks are laid by a light pressure of the hand and a light tap of the trowel, instead of by repeated hammering of the trowel to force the brick into place in stiff mortar. By the use of soft mortar we can lay enough mortar with one stretch of the trowel for half a dozen to a dozen bricks." Now, one stretch of the trowel with stiff mortar such as is used here will suffice only for three bricks, and it is evident, therefore, that since each trowel-charge of stiff mortar is of greater weight, and is more difficult to work, than the same charge of sloppy mortar, and will suffice for less than one-half the number of bricks, the weight of mortar and the work expended on a given area of finished brickwork laid on the British system must be much greater than a similar area laid on the American system. For 9-inch walls there is no doubt that the maxim, "Wet bricks and stiff mortar," must be retained, but it is possible that for walls exceeding 18 inches in thickness British builders may without much risk increase the speed of bricklaying by using more water in the mortar. We are of opinion that the use of sloppy mortar in the American fashion produces inferior brickwork to that erected on the British system, though we have never heard that American brickwork is unsafe, and modern factories are seldom required to be durable in the British sense of the term. But even for high-class British work the number of bricks laid per day should not be less than 600. — *The Builder.*

EL CAMINO REAL. — A California association is making an effort for the restoration to usefulness of "El Camino Real," the royal road, or the king's highway, which was travelled by the Franciscan missionary friars in the days, more than a century ago, before the "gringos" invaded the land. This road was the most direct route practicable between the pueblos and the missions. It ran through very many of what are now the counties of the State, and the supervisors in these counties have been asked to aid the movement. Many of them have consented. Little engineering science was used in the layout of the road. It sought a direct route where practicable, but it avoided obstacles, and it would be of little commercial use in these hurrying days. But the presidios, pueblos, and missions are "drawing" objects of interest to the tourists, and it is thought that interest would be increased if opportunity were afforded these later pilgrims to travel from mission to mission over the roads which had been trodden by the sandals of the friars and the boots of the Spanish soldiery. — *N. Y. Evening Post.*

WATER-LEAKAGE IN NEW YORK. — A recent writer in one of the daily papers of New York City ridicules the assertion that about seventy-five per cent of the Croton supply of water "enters the foundation-walls of the buildings along the many miles of mains." He shows that "seventy-five per cent of the daily delivery of New York's water-supply escaping into the ground, as they would have us believe, would play havoc with the streets by washing out the earth and causing the streets to cave in when heavy teams passed over these places." There is waste, of course, but the greatest amount (he insists) is in the older parts of the city. Yet it is these that "the heaviest trucks traverse, and a washout from a large leak would let a truck down." He would not be surprised to learn, however, "after an investigation, that, when the service-pipe is abandoned, the entire line from the buildings to the main, ferrule, or cock, is not removed, but only cut off at the curb line and the pipe hammered together — a custom by no means uncommon with contractors and plumbers — in which case there must be much and constant waste from these abandoned service-pipes." The writer proceeds: "I believe the Water Department had such experience only recently in Hanover Square. As an illustration, take the site of the new Custom-house at Bowling-Green. There once stood forty or fifty separate buildings, with as many service pipes. Have they all been removed all the way out to the street mains, and the taps in the mains plugged? Of course, the new Custom-house is not going to use all of those little fellows, but, no doubt, will make one, or several, new and larger connections." — *Fire and Water.*

APARTMENT-HOUSES NOT TENEMENTS. — The question before Justice Truax, at the Special Term of the Supreme Court, in the case of George Kitching against Kate C. Brown, was whether the defendant had violated a covenant in 1873 not to erect tenement-houses on his premises. Mr. Brown has erected three modern apartment-houses, each seven stories in height and each containing two apartments on a floor. Each suite has a parlor, dining-room, library, kitchen, five bedrooms, and servants' quarters. The buildings have every modern convenience. Justice Truax recently found against the plaintiff's contention that the buildings are tenement-houses, and within the definition of the Act of 1867, where such houses are "taken to mean and include every house, building, or portion thereof which is rented, leased, let, or hired out to be occupied as the home or residence of more than three families living independently of one another and doing their cooking upon the premises, or by more than two families upon a floor so living and cooking, but having a common right to the halls," etc. Justice Truax says the words "tenement-house," as used in the covenant, are to be construed according to their plain, ordinary, and popular sense, and not according to the definition given in the Act of 1867. "A tenement-house, then" (in 1873), continues Justice Truax, "as well as now, had a well-defined meaning. When one says to-day that a person lives in a tenement-house, he does not mean that such person lives in a house like the Nevada flats, and yet those flats are occupied by more than three families living independently of one another and doing their cooking upon the premises." — *N. Y. Times.*

AN ANCIENT TEMPERED COPPER PICKAXE. — An extremely interesting relic of bygone ages has just been dug up on the shore of Lake Gogebic, a few miles east of Ironwood, Mich., by A. C. Hargraves, of that location. It is a pickaxe of tempered copper that had apparently been used in prehistoric times by people dwelling along the lake. The metallic part of the pick is 23 inches long and about half an inch thick. It tapers to a point at either end and is as finely tempered as a piece of tool steel. At the centre is a place where the tool was bound by thongs to a handle of wood. It is so hard that a steel file makes no impression on the copper. The art of tempering the red metal is unknown at the present day. Occasionally tempered copper knives have been dug up in this region, but this is the largest tool ever found.—*Boston Transcript.*

NOTES AND CLIPPINGS. 16

IT is to be hoped that the assaults on the New York tenement-house laws, which are being made before the Legislature with extraordinary persistence and ingenuity, will not succeed, and the influence of all who wish well to their fellow-citizens, as well as of those who look merely to the selfish object of protecting their invested property against the burdens which pauperism and crime impose upon it, should be brought to bear in opposition to the speculators. The present law involves no hardship to any one, since it compels no one to build tenement-houses against his will, providing only that those who choose that form of investment shall conform to certain regulations, necessary for the health and morals of the public. We know from actual statistics that the very poor are more moral than the rich, but their modest virtue cannot be expected to resist the contamination which they have hitherto been unable to avoid, and it is the duty of the community to do what it can to protect them and their children from such contamination by such means as legislation can afford. Among these means, none is so effective as the regulation of tenement-house construction. Every one knows that the habit of poor people, especially those who are poor and young at the same time, of spending their leisure moments in the streets, is ruinous to their morals; yet the alternative, of spending their time in the foul air of their gloomy and unventilated tenements, is something which they can hardly be blamed for rejecting. To induce people to cultivate the virtues of home, their home must be at least tolerably attractive; that is, it must be so well supplied with fresh air and light that their physical natures will not instinctively revolt against it, and so protected against rude intrusion that the members of the family can have at home something of the freedom which they now seek outside. If these requirements are fulfilled, family life among the very poor can easily be made as valuable, as a civilizing agent, as it is among the well-to-do. In fact, very poor people, from the intimacy necessary in their crowded dwellings, and the constant practice of forbearance and self-sacrifice which their circumstances require, often develop a sweetness of disposition, and an intensity of mutual affection, which are rarely seen among the rich; and the work of encouraging this family attachment among the humble, and protecting it from contamination by evil associations, is, perhaps, the most important that philanthropy presents. To a very great extent the happiness and purity of family relations depends upon the planning of the dwellings in which poor people must be crowded together, and legislation which secures the general adoption of at least the simpler principles of good planning is the greatest benefit that can be conferred upon those citizens who have not the means of influencing for themselves the construction of the houses in which they must live.

IT must be remembered that every person, rich or poor, has a special interest in the improvement of tenement-houses. Every happy and contented family is an element of power and prosperity to the whole community, just as every outcast is a burden and a menace to it. Whatever tends to make people happy, by promoting their physical and moral health, and to make them contented, by preserving their strength to work for themselves and each other, adds to the productive resources of the State, and lessens its burdens, and no one can have followed the progress of modern sanitary science without observing the profound change which the spread of cleanliness and decency has effected in nearly every civilized country. Until recently, the beneficent effect of abundant water-service and efficient sewerage have been felt mostly among the middle classes, who have had money enough to provide the plumbing appliances required by the new ideas of decency; and the very poor, who form at once the most numerous class, and the one most in need of sanitation, as well as the least able to obtain it, have been neglected. Now, however, there is a strong tendency toward securing for the poorest people something of the advantages which others find indispensable. The present tenement-house law of New York is a result of this tendency, and to annul or modify essentially any of its important provisions would be to abandon the ground that has been gained.

MORE important, however, than the passage of such laws is their impartial enforcement, and it is this which, if the present law is maintained, must next receive the attention of its friends. A recent examination of the New York theatres, by the new Superintendent of Buildings, has shown that the laws regulating their construction have been, in many instances, shamelessly violated. It is needless to say that if the owner of one theatre can violate the law with impunity, other owners will obey it unwillingly, if at all, and the practice, in such constructions, will soon be simply a struggle to evade it. The summary closing of all theatres in New York which do not comply with the law in every particular would convey a most wholesome lesson to builders and real-estate speculators, and this, followed by a thorough inspection of all new tenement-houses, would not only protect their future occupants, but would encourage the better class of builders and owners, whom nothing disheartens so much, in their conscientious efforts to comply with the law, as the feeling that some competitor in business, with the advantage of corrupt collusion with an inspector, will be enabled to get away their tenants by the offer of rooms, equally attractive with theirs, so far as the tenant can judge, at rents which would not pay reasonable interest on the cost of a house built in compliance with the law.

EXPERT observers in New York think that the great speculation in real-estate, which has so long flourished there, has passed its climax, and that values, in many cases, will soon begin to recede. Such movements in real property are usually started by some important political or other change, and the consolidation of New York with the neighboring cities undoubtedly gave the first impetus to a speculation which has lasted until now. In Chicago, the settlement of the great strike a few months ago seems to have given a similar impetus to real-estate operations, and, according to the accounts, values of real property there, which have remained stationary for nearly ten years, are beginning to advance. Boston is the only large city in which nothing of the kind has yet been observed. With the exception of syndicate transactions in connection with office-buildings, there has for several years been very little movement in real-estate, and prices have, in most cases, declined during that period. Lately, however, rents have, in many cases, been raised, in consequence of a rather marked increase in demand for buildings of various sorts, and the prospect is that large amounts of money will, before long, be taken out of stocks, which pay less than three per cent interest on their present selling value, and put into real-estate of various kinds, the price of which has remained stationary, or has declined, within the last twenty years, while that of personal property has, in many cases, doubled, and which, with rents at present rates, pays easily five or six per cent on the investment. It is not likely that there will be anything like a general speculation in Boston real-estate, unless one should be started by the annexation of the neighboring towns which an energetic party is trying to bring about; but a slow advance in values of land, and an increased demand for store and house property in good locations, seem extremely probable.

PERCEIVING from the tenor of the remarks we made about their affairs a week or two ago that we had no disposition to give overmuch credence to the justifiability of the indecent newspaper assaults that have for many months been made upon their professional reputations, Messrs. Horgan & Slattery, architects, of New York, took the trouble to bring to us a number of documents that tend to prove that they have not received at the hands of Mayor Low the consideration to which their claims seem to entitle them. The papers they exhibited to us would seem clearly to show that they deserve, at least, a fair hearing, while this Mayor Low has declined to give them, basing his objections, as we understand the situation, on the, to him, evident fraudulent intent or the monumental professional incapacity of architects who prepared plans for an armory building intended to cost four hundred and fifty thousand dollars, the lowest bid upon which was over six hundred thousand dollars. We ourselves, believing the Mayor must be right, agreed that so great a disparity between appropriation and the lowest bid was reason enough for breaking off dealings with architects so incompetent or so untrustworthy. But the documents before us show that, after receiving the instruction of the Armory Board, Messrs. Horgan & Slattery, on December 11, 1900, sent in preliminary drawings accompanied by their approximate estimate of six hundred thousand dollars. Between this time and November 19, 1901, they were in constant communication with the Board of Armory Commissioners, working up their drawings and specifications, without a word of advice that it would be needful to reduce the cost, and on that date the Board voted that the contract with them should be finally executed. Then, two weeks later, when the contract was brought to them for signature they first found out that the actual appropriation was to be much less than six hundred thousand dollars. On this statement of facts it is not surprising that the bids actually received in the following January exceeded the allowable ten per cent of excess to which our remarks referred, and it seems to us that the architects should be given a fair chance to prove their allegations.

WE have no desire to stand sponsors for Messrs. Horgan & Slattery whether as men who have political affiliations of one sort or another, or as architects of undisputed ability, but we do feel that they are entitled to fair play, and the reckless newspaper scribblers have made so much fun out of the sonorous slipperiness of their names that a notoriety has been thrust upon them that could not have befallen, say, Messrs. Green & Brown, no matter what political affiliation the latter might have had. And these newspaper jibes and floutings have been of such a character that reply to them was impossible for men who had any respect for themselves and believed that their real acts and motives fell within the limits of professional propriety. We will say frankly that we share the misgivings of those who have imagination when we consider the possibilities of the interior of the Hall of Records being carried out with the exuberance of effort that is shown in a design published elsewhere in this issue, but that exuberance need not of necessity intervene and it is not impossible that Messrs. Horgan & Slattery already perceive the desirability of associating with themselves — supposing that the contract between them and the city is not to be cancelled — a known, or a nameless, somebody who really does understand the style in which Mr. Thomas was working and the refinement of which it is susceptible. As to the County Court-house matter, to which we also referred, it is to be remarked that judges may know quite as much about law as a Corporation Counsel, and that three of the justices approved of the architects' plans for altering the building and found no reason why the work should not be entrusted to them.

THE Boston *Herald* has done an excellent work in calling attention to Mr. John DeWitt Warner's interesting lecture on the Abuses of Advertising, from which our cities are beginning to suffer greatly. London, where every omnibus is so covered with advertisements that it is difficult to find the inscription showing its destination, and where a patent-medicine vender was recently allowed to cover Nelson's flagship, the "*Foudroyant*," with advertisements of pills, is perhaps the worst existing example of the abuses in question, but New York is now not far behind; and Mr. Warner calls upon all who care for the artistic interest of our cities to unite their influence to secure the regulation of advertising in public places. In France, where every public advertisement must have a revenue stamp on it, proportionate in value to the size of the placard, this tax alone brings in seven hundred thousand dollars a year; yet the tax, on an advertising card of reasonable proportions, is very small, and its effect seems to be to reduce the size of placards, and to promote endeavors to make them artistically attractive, rather than to reduce their number. Naturally, the man whose business will not warrant the expense of buying stamps for very large advertisements is likely to use some thought in the attempt to call public attention to smaller ones, and it has not taken long, in France, to discover that artistic beauty attracts many more readers than the vulgar obtrusiveness of enormous size. As a consequence of this, hundreds of advertising posters are to be seen in France which are models of beautiful coloring and clever treatment of effect; and artists of high reputation are employed to design them. In many cases, the posters are of so much merit that they are sought by collectors, and bring a price, as specimens of artistic workmanship, far beyond their cost. In Switzerland, whether in consequence of a similar law, or through the instinctive decorousness of the Swiss, very beautiful posters are seen everywhere, and the same is the case in Belgium, where public art is an object of exemplary devotion. In this country, where rival magazine covers, and occasional placards, show sufficient ability on the part of designers, the demand of advertisers is generally for something obtrusive and cheap; and it would be well worth while at least for Boston and Cincinnati, the two American cities in which, perhaps, the love of beauty is most generally diffused, to try the French method of regulation, which would at least pay for itself, and could do no harm, while it might do much good.

A BUILDING fell the other day in Chicago through the effect, as we are told by the daily papers, of "frost leaving the ground." That this reprehensible conduct on the part of the frost was the sole cause of the catastrophe is made certain by the fact that the structure was begun in December, the foundation being laid, apparently, on frozen ground, and everything remained firm until the ground was "softened" by warm weather. Then the foundations settled, and the building fell. It may be remarked that experienced architects, in Chicago as well as elsewhere, have long been acquainted with the fact that this result usually follows the "softening" of the ground under foundations laid on frozen soil; and, as there seems to be no way of preventing the frost from "leaving the ground," they take the precaution to lay the foundations of their buildings on unfrozen ground, by digging down through the frozen crust, if necessary, and bank up with earth around them in winter, to prevent the ground from freezing under them after they are laid. Warm weather, naturally, does not affect foundations laid in this way, and the method may be commended to the attention of architects and others who suppose that frozen soil is a proper material to rest a building on.

THE new Germanic Museum of Harvard University, which begins its career with a magnificent collection of casts of German works of art, presented by the Emperor of Germany, is to be still further enriched by the gift from the Federal Government of Switzerland of a set of casts of Swiss art, mainly taken from objects or casts in the National Museum at Zurich. It is hardly necessary to say that Switzerland contains many precious bits of architecture and sculpture, which will add greatly to the interest of the collection in the Museum; and the thoughtful courtesy of the Swiss Government in making the gift will be nowhere more highly appreciated than in Harvard University.

THE people who are always holding American architects up to scorn for their ignorance of the "solid" and "incombustible" nature of Continental construction might with advantage be occasionally reminded of the great fires which occur in European cities. One of the most destructive of these, about which little is known in this country, was that in the Antwerp bonded warehouses, last year, in which several connected buildings, filled with goods, were completely destroyed in less than four hours, with a loss of about thirty million dollars. The buildings were old, and made no pretence of fireproof construction, although the timbering was heavy, some of the beams, which were completely burned through, being a foot square in section; but the difference between the rapidity with which the fire actually ran through and destroyed them, and the behavior which newspaper correspondents usually attribute to all Continental constructions in such cases, is interesting to note.

JOURNAL SKETCHES IN CHINA. — I.

WITHIN 100 miles of the mouth of the Yangtse the sea becomes yellow and the water opaque from the mass of mud brought down by this great river. The Yellow Sea, the name of which I had learned in my early school-days, was now clearly understood, so much better is a single object-lesson than pages of dull description. With the understanding of this came also a realization of the mighty changes which are slowly taking place in the wearing away of land-surfaces and the filling-up of sea-bottoms through the erosive energy of water. Here was this great mass of water, 100 miles from land, made noticeably yellow by the mixture of fine sediment brought down by the river. I could not help reflecting that if, in the future, a yellow flood of human detritus should overrun Europe and America it would render civilization just as opaque and make shallow the great depths which mark the intellectual supremacy of our race to-day.

We anchored at midnight some miles within the mouth of the river and at dawn started again, still, apparently, in mid-ocean, as no land could be seen on either side. The river at this point is 40 miles wide, and one realizes its magnitude when he is told that for 800 miles the river is deep enough to float the largest ships. We sailed for an hour and more and the expanse of water seemed illimitable. Gradually we neared the southern shore, and long, low stretches of land came in sight. The scene was desolate to the last degree. The vessels we passed were numerous and quaint; we had seen such craft figured in books and were familiar with their models in the museum at Salem, but here were the veritable objects: fishing-boats, trading-vessels, engaged in the enormous coast-wise traffic, and war-junks. The fishing-boats had a huge dipping-net standing up like a sail on either side of the boat, and not on one side, as I had noticed in Japan.

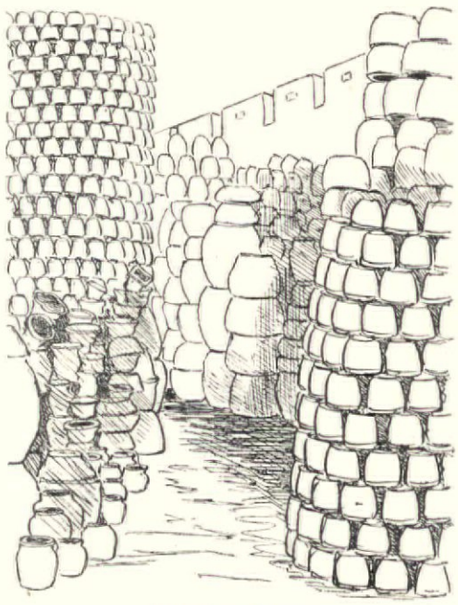
My attention was soon attracted to the peculiar features of the land, which was covered, so far as the eye could reach, with low mounds. It presented the appearance of a salt-marsh covered with hay-cocks. My first impression was that they were prehistoric mounds, and consequently offered a great field for the archæologist. I soon learned that these mounds, extending to the very horizon, were simply ancestral tombs, or burial places. Here, then, we had, even before landing, a glimpse of how a baleful superstition could arrest the progress and development of a people. Not only was a vast amount of arable land thrown forever out of cultivation by these surface-consuming sepulchres, but the necromancers insist that no road shall be built through them, nor must the shadow of a telegraph pole or wire fall upon them. One no longer wonders that there are so few roads in China. Some slight respect might be felt for this superstition if these mounds showed any evidences of tender regard or care for the dead. A closer examination, however, shows them to be in the most neglected and dilapidated condition. The contrast between their treatment and the treatment of similar places in Japan, where graves 300 years old even are still freshly decorated with flowers, is striking.

After sailing for several hours, entertained by the diversified craft on the water and depressed by the dismal and monotonous landscape beyond, we turned into the Shanghai River, and, crossing the bar, after another hour's sail, reached Shanghai and came to anchor. I noticed the little boats as they came out or floated by were brown with dirt and grease; indeed, the woodwork reminded one of the inside of a hut for smoking bacon. My standards of comparison were always with Japan, and this was certainly unfair, but there came to me the memory of Japan, where the woodwork of boats recalled the cleanliness of a Quaker kitchen and even the sewage-buckets came back from the country scoured like milk-churns. The memory of Japanese cleanliness rendered all the more shocking the exceeding dirt of this people. The foreign city of Shanghai, with its beautiful buildings, fine streets and parks, has often been described, and the contrast, as one passes from its spacious avenues to the dirt and squalor of the Chinese quarter, is appalling. It is difficult

Gateway, Native City of Shanghai.

to realize that this great object-lesson of order, elegance, cleanliness and comfort is looked upon by the Chinese with supreme contempt.

When I looked out of my hotel window the next morning a glimpse of one form of Chinese architecture was in view just across the street. It was a typical doorway of a business enclosure, and a sketch of one is a sketch of all. The various mouldings and the ornaments over the doorway were very elaborate, and nothing short of a painstaking drawing or photograph could do justice to the work. The little groups of carved human figures and pheasants, brightly colored, and tinsel-like accessories, might have meant something to the Chinese brain, but they looked trivial and insecure for



Pottery Yard, Shanghai.

the entablature of a doorway. Whole streets in the foreign quarter are lined with these rather high, windowless walls. Some of them had stone or glazed pottery panels with figures of flowers moulded in high-relief. The ridges of these walls were gracefully turned in broad curves, and imbricated coping of roofing-tiles, bedded in cement, presented features that our architects might study with profit.

After breakfast I hunted up Mr. Edward B. Drew, an officer in the Chinese custom-service to whom I had a letter and who during my short stay in Shanghai greatly facilitated my work. His father kindly offered to go with me to the native city of Shanghai. It should be explained here that the Chinese towns are surrounded by high walls having several gates which are closed at night. The irregular lanes which function as streets, the filth and noise of these overcrowded communities are intolerable to our race, and one, therefore, finds at Shanghai, Canton, Tientsin and other cities a concession where the foreigner lives apart, with his own ideas of streets, buildings and cleanliness. This, then, was the foreign city of Shanghai with its imposing buildings; villas with well-kept lawns and gardens; broad avenues and open parks modelled after our own ways and presenting the leading characteristics of our well-ordered cities. The dwellings, with their open character and their broad verandas, have just enough flavor of native architecture to add piquancy to the effect, and the Chinese nurses, with strange coiffures and silken garments of curious fashion, accompanying little English boys and girls, present a continual series of interesting sights to the foreigner when he first lands. Then in contrast is the ancient walled city of Shanghai, out of whose dungeon-like gates swarm a living stream of natives, reminding one of a colossal ants' nest. As we neared the city the swarm and bustle increased — an eager, active crowd, pushing, jostling, shouting and intent on getting somewhere with their multifarious loads swinging from the ends of their carrying-poles, which they deftly guided through this dense current of humanity.

The grim walls of the city towered just beyond a bridge which spanned a narrow canal filled with all manner of liquid impurities. The walls were crenellated for cannon, but no cannon could be seen, and with their massive thickness and rounded buttresses they presented a most formidable appearance. Outside the wall were piled to a great height pottery jars of all descriptions. It was a veritable lumber-yard of pottery. There must have been thousands of pots and jars in these accumulations. They were piled up in regular and solid masses nearly to the height of the city's walls, — huge water-jars, bathing-tubs, flower-pots, etc., all of coarse pottery with brown or green glaze. One wondered if they ever tumbled down, and wondered still more how they had been piled up to such a height and so securely.

As we entered the city the crowd became denser and such a swarm of shabbily dressed men and boys I never saw before. Now and then a mandarin with his brocade and silken vestments rendered more striking by contrast the squalor of this unkempt crowd. A few women and children were being hustled in this living stream which incessantly flowed in and out of the gateway. We passed through by dint of much dodging and became one with the innumerable mass that filled the irregular-running streets. Palanquins, each with a number of bearers swinging along and crowding obstructors to the wall; peasants with buckets hanging from the ends of long

carrying-poles containing the sewage of the city, rudely sweeping by, shouting and by no means careful whether they brushed you with their filthy receptacles or not; water-carriers moving rapidly along with slouching step in cadence with the oscillations of their carrying-poles, their legs fairly buckling under them from the enormous weight they were bearing, and calling out in curious cries to make a way; wheelbarrows loaded with market produce and human freight as well, awkwardly jamming into the crowd, all combined, made an impression never to be effaced. Everybody was dirty, and the surroundings were dirty and old. The city looked as though it had never been swept or cleaned, and it never had. Mediæval microbes and prehistoric odors were always in evidence; many buildings going to ruin and, apparently, nobody with time or interest enough to arrest the decay. Indeed, in my brief experience in China, I do not recall the sight of any one repairing or cleaning a building.

The street sights, as in all Oriental cities, were of abounding interest. Here was a group of little boys gambling with copper cash and wildly and noisily gesticulating. The Chinese are born gamblers and their various methods and intricate games of chance render poker, to them, a kindergarten game. In a little open space, wet and muddy, was a wreck of a street juggler, ragged and dirty to the last but one degree, with an assistant reaching the last degree of dirt and dilapidation. The properties with which they played were equally squalid — a basket, a rag, a wooden doll, a cup, a few bamboo tubes and other junk-shop material. Now, the marvel was to see these vagabonds, with vagabond material, play the most wonderful sleight-of-hand tricks. After seeing these wrecks perform, I could well believe some of the marvellous stories about the Indian jugglers. A circle of admiring men and boys surrounded them, and despite the danger of contagion, for at that time the people were dying by hundreds of small-pox and one passed on the street cases showing full efflorescence, I joined the ring. The ancient trick of sword-swallowing was done with a long rusty sword and there was no trick about it, for the rusty blade was literally thrust down the stomach. The man had picked me out as a victim and with body inclined and straightened he came directly to me and held out his hand, nor would he draw the sword till I had given him some money, the crowd, meanwhile, eyeing me and derisively shouting. When he withdrew the sword tears flowed from his eyes and copious phlegm ran from his mouth. It was a most painful and disgusting sight.

Our guide was to take us to a famous tea-house, and the remembrance of the Japanese tea-house, with its exquisite neatness, simple and satisfying surroundings and quiet demeanor of the attendants — all girls — was fresh in my mind, so I looked forward with interest to the sight of a Chinese tea-house and a famous one at that. I felt assured that here, at least, were to be seen some attractive features in the way of cleanliness and pleasant surroundings — some contrast to the squalor through which we had been roaming during the morning. I fully expected to have a new experience, and here was the tea-house: a two-storied building in typical Chinese style, certainly quaint in its architecture and recalling the pictures one sees rudely depicted on blue-and-white china. The building rose from the centre of a pond and was approached by a zigzag bridge. Now, the house, bridge and pond were in an equally dirty condition. The water was covered with a green slime and emitted foul odors. We crossed the bridge, entered the building and found our way to the second story. Taking a seat at one of the tables we ordered the usual tea, which was brought to us, by a male attendant, in large covered porcelain cups accompanied by a tray full of unsavory looking cakes. If there is one evidence above another of the absence of all artistic tastes among the masses in China the appearance of the food alone might be offered.

In Japan the little street booths exhibit a variety of cake, rice-balls with fish on top, and confectionery, and these are all made in tasteful forms and moulds. The Japanese not only enjoy the simple art displayed in all such matters, but seem capable everywhere of fabricating tasteful-looking objects. The Chinese tea was delicious, far more to the foreigner's taste than is the best of the Japanese. At a table near us were three mandarins and, judging by their fine clothing, evidently of the better class. They looked at us inquiringly for a while and finally one of them arose, crossed to our table and shook hands with Mr. Drew, who thereupon presented him to me as one of the famous class of Hartford students who were all recalled by the Government while in the midst of their studies. The two others then came to our table and an interchange of introduction followed. Mr. Drew explained to them my desire to see the interior of a Chinese house, and one of them, turning to me, said that he and his companions had all been so kindly treated in America when students at Hartford that they would be only too pleased if they could be of any service to me. Gladly accepting their kind offers as hosts and guides, I promptly dismissed my guide who had brought me hither, and under their lead at once started off on a round of investigation. It was a rare and interesting experience to ransack the native city with three mandarins dressed, of course, in their full Chinese costume, with their long queues hanging down behind. All of them spoke English without an accent; they were even familiar with our peculiar New England idioms and even with our slang. As an illustration: I stopped to buy some trifle at a shop, when one of them said, "Oh, come along, Mr. Morse, don't bother with him, the fellow's giving you taffy." It was, indeed, a rare opportunity and it was through their help that I was enabled to make many sketches of house-interiors. One of them kindly invited me to his home. How he ever found his way there is a mystery to me to this day. It was a long walk through a tangled labyrinth of narrow and exceedingly crooked streets. On entering his house we apparently passed through the side of a shop and came to an open courtyard. From there we passed into a kind of reception-hall used by two families in common. A side entrance from this led us into a more secluded reception-hall. His little sister came out to meet us and I held her for a moment, but she seemed very shy, as well she might, for she had never been so near a "foreign devil" before. A little brother, equally shy, stayed by me for awhile despite his fears. I was shown rapidly through the ground-floor of the house, including the kitchen and servants' quarters, but, as my friend had invited me to dinner the following day, made only brief memoranda of the points that had interested me. The most serious matter was the very primitive and objectionable feature connected with the sanitary arrangements. I have dealt with this subject elsewhere,[1] but must insist that in these respects the Chinese are degraded to the last degree and one wonders, if such conditions prevail throughout the Empire, how the nation should number 400,000,000, whereas if they belonged to the same species with ourselves they should all have been swept off the face of the earth centuries ago. Entering a room called the study, or library, we were invited to sit; a servant brought us a light refreshment consisting of fried peanuts, oranges and a little root which had a delicious crisp taste. The root was dug from the river-mud and was quite new to me. I enjoyed it, not having seen the river. Wondering how I should dispose of my orange-peel and peanut-shells, I was told to throw them on the floor! The floor, it may be added, was apparently mother earth — damp, cold and nearly black in color; in fact, a continuation of the street-surface. Doubtless, the floor was tiled; the dirt, however, obscured all traces of it. It was late in the afternoon when my companions guided me to the gate of the city by which we had entered in the morning. After passing through a densely settled Chinese area and coming into wide streets and fresh air it was like passing out of a noisome pit into health-giving daylight. Outside the city-walls there is an immense Chinese population, outnumbering the foreigners thirty to one.

The next morning, one of my Chinese acquaintances of the day before came to the hotel to guide me again through the entangled channels of the native city and to take me to his house to dinner instead of to the house where I was first invited. We entered by a different gate, yet the same throng of people were pouring in and out, and the walls about the gate had the same huge piles of pottery in great blocks. We traversed the same narrow and tortuous alleys, were assailed with the same odors and hustled by the same rude hurrying crowd of water-bearers, sewage-luggers, market-men and a hundred other varieties of two legged carriers. It was a puzzle as to what they were all about and why they were in such haste. In the toting of heavy loads one might imagine the hurry to get rid of the swinging weight, but everybody seemed to be impelled by a restless or nervous energy, and yet no race shows more the absence of what we call restlessness or nervousness than the Chinese.

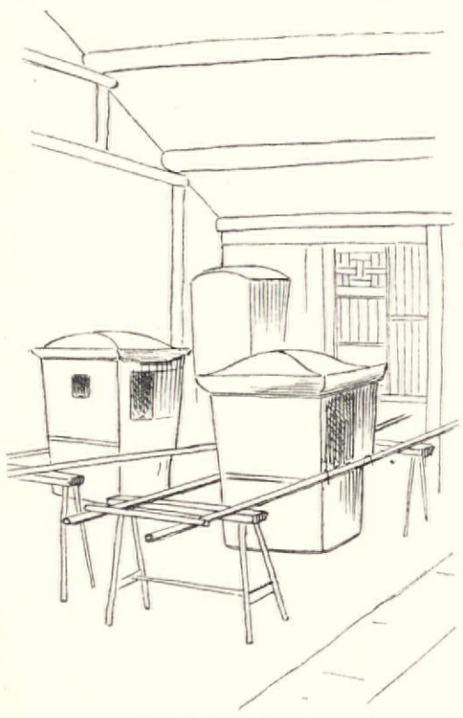
A second view of the city opened new sights. A peculiar effect is produced by the shop-signs, which are hung at right angles from the shops and when free hang vertically, as the Chinese characters are read in vertical lines. These signs were of all sizes and the characters were in gilt or red. Over the door and on the sides of the posts were strips of paper upon which characters were written.

The narrow streets curving often and the projecting signs, with the close crowds filling the entire thoroughfare from side to side, give one a smothered sensation. From the open character of the shop-front and the many occupations going on in the street one is brought into most intimate contact with the people. Porcelain-shops and metal-shops seem to predominate, probably on account of the cleanliness of the "blue and white," and the hammering noise emitted by shops of the other kind. Restaurants were numerous, but the unsavory messes offended the eye as well as the nose. On our way to the house where we were to dine we stopped at a few Buddhist temples, and these were so dirty and dilapidated that any description of their lamentable condition would seem exaggerated. It was shocking to see the root of a tree prying off some delicate bit of stone carving from an entablature and no one in the land with wit or enterprise enough to cut off the offending root and save the structure. We stopped at one house to invite a companion of the day before to dine with us. He was still abed, though it was past ten o'clock, and so, while waiting, I had an opportunity to see a coffin-maker's place, for that was the trade of his family. Whether the occupation of coffin-making is considered respectable in China I do not know, but a friend of mine, whose family name is Coffin, on being presented to our Chinese minister, Mr. Wu, brought out the brusque response that he ought not to have such a name. I examined the stock-in-trade. The coffins were huge affairs, the best ones being made of thick planks. In these chests the body is closely packed with powdered charcoal and may be kept in the house for weeks before final interment. In passing some carpenters at work I noticed that many of the tools were identical in form to those used by the Japanese; the wood-lathe was used in the same way; the blacksmith's bellows, in the form of a large square box with a square piston working back and forth, was the same. The blacksmith, however, stood at his work and the anvil was raised from the ground. In Japan the blacksmith sits on the ground and may be seen pulling the bellows with one foot, while the other foot is bent under him, the anvil being on a level with the ground, the helper, however, standing at his work.

[1] "Latrines of the East." *American Architect*, March 18, 1893.

China, I soon realized, was a land of tables, chairs and bedsteads, and men stand at their work. Their legs are long and well formed, and the Manchus, as a class, are physically well built. It is a common impression with many that the short and often bent legs of the Japanese are due to their custom of sitting for many hours at their work with their legs bent under them. If it could be proved that the shortness of their legs was due to this universal custom of sitting, which I do not believe, here would be a good example of the transmission of acquired traits.

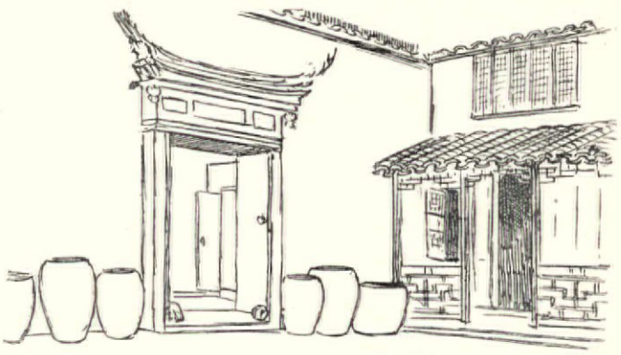
As we approached the place where we were to dine I was told, on inquiry, that the house represented a dwelling of the better class. I asked my host if there were any streets or regions in the city specially noted for their finer houses, and he said, "No; you will find the house of a rich man adjacent to the hovel of the poor." In other words, there is no West End or Fifth Avenue, so to speak. This condition was precisely what I found in the cities of Japan. The entrance to the house was not unlike the one we visited the day before. We first entered an open court surrounded by a high brick wall, which, in turn, opened into an inner court, on our way passing a large room in which were a few palanquins, or chairs, as the foreigners call them — a carriage-house, in fact. In entering the inner court-yard we could look into the general reception-room directly opposite the main entrance. On the sides of this courtyard were rooms which were designed as studies, or libraries. A tiled roof supported by upright posts projected from the eaves, and had there been a floor beneath, a veranda would have been provided for these various rooms. The courtyard was paved with square stones and was fairly clean. The main entrance to the courtyard had an elaborate entablature, too intricate for me to sketch in the limited time at my disposal. At night all the doors are closed and barred, and this feature, with the high surrounding walls of brick, presented a marked contrast to the unprotected and open character of the Japanese house. On either side of the courtyard entrance were huge pottery jars for the purpose of holding water. From the courtyard we entered the library, and here the family immediately gathered about me, all except a daughter, aged seventeen, who was as much a prisoner as any felon. Later I was shown through the house, and having seen several rooms on the ground-floor, I asked particularly to see the girl's bed-chamber, which was in the second story. The appearance of my own daughter's chamber was recalled, with its pictures and souvenirs on the wall and the dainty trifles which brought up so many pleasant memories of parties, picnics and journeys abroad. My host regretfully told me that it was impossible to grant this reasonable request; if I were allowed even a glimpse of his sister's chamber it might be reported by the servants and her chance of marriage might be imperilled. He further told me that even the lower classes were particular in these matters. Even the most intimate friend of the family would not be allowed to go upstairs. Until this experience I never fully realized the condition of women of the more favored classes in China, though their unhappy



Palanquin House, Shanghai.

lot has been repeatedly described in works on the subject. At the outset the girls' feet are compressed in a cruel fashion, so that a dull pain is endured for a year or two, and in some instances mortification of the parts takes place and the child dies; with no recourse to books, as she is unable to read or write; at the age of twelve or thirteen immured in the house like a prisoner, with the privilege, however, of an occasional visit to some intimate female friend of the family or a near relative and this visit made in a closed palanquin; at marriageable age compelled to unite with a man she has never seen and knows nothing about and consequently with no choice in the matter. All of which you say is barbarous, and so do I. This, however, has been the custom for centuries and a custom in China is a thousand times more unmodifiable than with us.

Bearing in mind this custom of rigid exclusion of the women from every walk of life for ages, let us try faintly to imagine how to them



Courtyard: Private House, Shanghai.

must appear an aggressive female missionary boldly walking the streets in open daylight in a garb which seems highly disreputable, not to say indecent, to the Chinese, and endeavoring, in very deficient lingo, to induce the people to come to her compound and listen to teachings as alien to Chinese beliefs, crowded as they are with superstitions, as are the teachings of Ingersoll to the strictest Presbyterian doctrine. I could not help picturing what the effect on our people would be with the conditions reversed, and if a strange and powerful people by armed force should impose upon us a treaty in which had been surreptitiously inserted a clause whereby their missionaries might own property and preach their dogmas throughout our country. Furthermore, for just comparison, the female proselytes of this cult should be seen in our streets with painted cheeks, dyed hair and garments extremely short at either extremity, and riding savagely down the street on a bicycle. Whatever horrid lie might be told about such people would certainly be believed by our masses, just as the shocking lies told about our missionaries are fully believed in China. It can be stated, without a shadow of doubt, that our female missionaries present quite as shocking a sight to the Chinese as would be to us the apparition I have just described. Now, we all know and admire the heroism which prompts our women to part from family and friends and enter into the arduous work of "converting the heathen." In their work of introducing a new religion, the propriety of which many question, they teach them the laws of hygiene, proper medical practice, the virtue of telling the truth, of being prompt, and set before them the living example of self-sacrifice and devotion for the good of others, and yet these Chinese savages have brutally undone all these workers have accomplished, not only by murdering the missionaries, but by slaughtering the native converts by thousands. It is a pitiful tragedy, and yet, judging from the outbreaks within a year in New York, Ohio and Louisiana, just such tragedies would be possible in our blessed land, if the conditions were reversed.

One of the reasons why the Catholic Church attains greater success than the Protestants in China is that its missionaries are men, its preachers are men, the Jesuit dresses in Chinese garb, he lives among them and becomes one of them; he is careful not to interfere with their superstitions only so far as these interfere with his own, and is especially careful not to inveigh against the foot-crushing mutilation. His incense-burning, bead-counting and picturesque ritual does not widely differ from the Buddhist. Kaempfer, when he went to Japan, as surgeon to the Dutch in Nagasaki, on seeing Buddhistic worship for the first time insisted that it was the devil simulating Christ. "*Diablo simulante Christum.*" Whatever the cause, the results attained by the Catholic missionaries far outstrip those of their Protestant — I was about to say brethren, but there is no brotherhood between these two great branches of Christianity. Not only are the intelligent Chinese perplexed at the variety of creeds presented by the Protestants, but they cannot in the least understand why the French should insist upon forcing the Jesuits into China, having kicked them out of their own country.

EDWARD S. MORSE.

[To be continued.]

LIGHTING THE PYRAMIDS BY ELECTRICITY. — The Egyptian pyramids are soon to come out of their darkness of 5,000 years, and will be accessible to all tourists. General Director Maspero, of the society which has in charge the preservation of the antiquities of the country, has been experimenting with the electric-light, and began his work on the Temple of Karnak, at Thebes. The experiment met with so much approval that he has decided to light the inner passages and catacombs of the great pyramids. This will provide Egyptian tourists with new attractions, and they will be able to penetrate to the innermost recesses of the pyramids. The lighting will be of especial value to women, who have confined their investigations of the pyramids of the left shore of the Nile to climbing up on the outside, as they were afraid of the intense darkness within. With the introduction of the electric-light the tombs of the Pharaohs will be accessible to all. — *N. Y. Evening Post.*

THE ARCHITECTURAL TREATMENT OF BRIDGES.

AS we have within recent months published a considerable number of photographic views of bridges that had been more or less successfully handled from the standpoint of artistic design, our readers may welcome an account, presented by the *Builder*, of a lecture given by H. H. Statham at Carpenters' Hall, London, on "The Architectural Treatment of Bridges."

"He characterized the subject as being essentially a modern one, as until recently bridges had been regarded as purely utilitarian structures; even the mediæval bridges which we have regarded as picturesque were, to the men who built them, only the best practical method of building according to their knowledge and requirements. Recently there had arisen a perception that a large bridge in a city might be an important addition to the architectural character of the city. A solidly-built arched stone bridge was in itself a structure naturally beautiful: it was only when we began to "ornament" it that we might run the risk of spoiling it. The old-fashioned bridges with narrow spans and semicircular arches were the most picturesque; but the demand for larger spans as our traffic grew more crowded and river-craft increased in size rendered it no longer possible to build bridges in this form, and led not only to wider arches, but to the introduction of steel spans, either with stone or steel piers. Steel bridges were a practical improvement in facilitating the combination of wide spans with low gradients; but owing to their thin lines, they could never have the grand and monumental effect of a stone bridge, and they had the additional disadvantage of requiring constant painting, with all which they could not have as long a life as a granite arch. Then there were railway-bridges, which were a separate problem, having to be constructed to fulfil special conditions in carrying heavy loads moving at great speed; so that structures which were satisfactory for ordinary roadways would not suffice for railways.

"Bridges might be classed under three heads: (1) Stone arched bridges; (2) steel spans with stone piers; (3) steel spans with steel piers. We might add a fourth class, now supposed to be rather *passé*, viz, wooden bridges. These, like the stone arched bridge, were almost invariably picturesque from the very nature of their construction, as was shown in the instance of one of the timber viaducts originally built on the Great Western Railway; but for railways they had not the quality of stability and permanence, besides offering danger from fire, and it could not be supposed that any such viaducts would in future be erected on English railway-lines. But for small bridges in country places timber was still a suitable material; such bridges also harmonized with the landscape; and it was much to be regretted that some of these picturesque and perfectly adequate wooden bridges on the upper Thames were being removed and replaced by iron ones, which might or might not have a longer life, but which were certainly not such agreeable or suitable objects in a rural landscape. Steel bridges on a large scale might be classified under the heads of beam bridges (or what engineers would call "girder bridges "), suspension-bridges and trussed bridges. He used the term "beam bridges," because such bridges were merely the application of the beam system of bridging an opening; laying a rigid beam across which bore vertically on the two points of support. A lattice-girder was, no doubt, a trussed construction within its bounding lines, but regarded as a whole it was a beam; it acted as a beam; and it was, or ought to be, no more offensive to taste than a wooden beam performing a similar office. The Britannia tube bridge, in another form, was a typical beam bridge; and, with its massive and simply treated towers, was a fine object. Suspension-bridges, like stone arched bridges, had the advantage of being almost necessarily beautiful in themselves, if let well alone. There was always beauty where a structure expressed, as it were, the forces of nature, whether in the balanced curve of the arch or the catenary curve of the suspension-chain. The practical drawback to suspension-bridges, for heavy traffic, was, of course, their lack of rigidity. Of what might be called trussed bridges the most important form nowadays was the cantilever bridge, of which the Forth Bridge was the most remarkable example, and by means of which greater widths had been bridged than had ever been attempted before. (The principle of the cantilever bridge, with its two arms and the straight length between, was illustrated by the photograph of two men seated in chairs and supporting a third man in the air between them, a whimsical but apt illustration originally made under Sir Benjamin Baker's direction.) The cantilever principle, though only recently used on a large scale by engineers, seemed, however, to be a method that had recommended itself to uncivilized man, as was shown by photographs of a rude Chinese bridge and another made by North-American Indians, both of which were cantilever bridges in a crude form.

"Of all these classes of steel bridges it might be said generally that the less attempt at ornament on them the better. It was very difficult to put any ornament on a steel bridge which would not have a more or less gewgaw effect; the undisguised structure was far better and more sensible. *Pure structure was never in bad taste;* and the anathemas often made against every kind of engineers' steel bridge by æsthetic persons were very absurd. If the objectors knew a little more about structure they would find the steel structure in itself interesting, instead of regarding it as an abomination. Unfortunately, the engineers were going rather in the wrong direction; they were spoiling this class of bridge by attempted ornament. Taking suspension-bridges for instance, it would be seen from the illustrations how extremely simple were the Menai Bridge, the old Hungerford Bridge (now at Clifton), and the old Hammersmith Bridge; while in the new Hammersmith Bridge they had gigantic cast-iron foliage ornament of the most hideous kind, and such as would be enough to vulgarize any structure. Contrast with such a work the Auteuil Bridge at Paris, with its plain structure in the spandrels, a little graceful ornamental treatment in the balustrade (where it was quite in place), and the fine stone sculptured figures on the piers, modelled by some of the first French sculptors of the day. Was not the contrast rather a humiliating one for London?

"The Tower Bridge was referred to as one which was a combination of suspension-bridge, beam bridge, and lifting bridge. It was an unfortunate mistake to suppose that because it was near the Tower it was to be mediævalized. The way to harmonize with mediæval structures was to do as the mediæval builders did — build in the best way known and practised at the time. A steel structure honestly shown would have been far more in harmony with the Tower, in the true sense, than a piece of sham mediævalism. The first design for the Tower Bridge, however, by the late Sir Horace Jones (a view of which was shown) was much better than the one actually built, as it was simpler and more massive in effect, and the towers were genuine solid stone structures. Even in this design, however, there was a want of simplicity, the towers being weakened in effect by unnecessary decorative windows and other details. In the actual bridge these defects were much increased, but the greatest mistake of all was that these apparently massive towers were a complete sham, with no foundation at all, the walls being carried on steel girders; and before the bridge was completed for opening he (the lecturer) had looked under the walls of the towers, which stood over empty space. It was perhaps the most glaring instance of sham in building that had ever been seen. A sketch was shown on the screen to illustrate how such a bridge might be built so as to be a solid and genuine structure, the horizontal girders carrying the tie which connected the suspension-chains being laid on the top of massive towers of stone brought out on each side as buttresses, and the ends of the horizontal members, resting on roller-beds brought out to the front of the buttresses, so that it could really be *seen* what the suspension-chains were attached to, instead of leading them through openings in the masonry as if they rested on it. The mechanism for raising the bascule leaves of the bridge, of which a section was shown, was a beautiful and simple contrivance which could not be too much praised; as an engineering structure the bridge was a splendid success; as an architectural design it was a flagrant piece of pretence. Even in regard to plain steel construction, there was such a thing as good and bad design. Contrast the elevation of the Sukkur Bridge, in which there seemed to be no ruling element of line or disposition, as if the girders were tumbled together, with that of the Forth Bridge, which, by comparison, was a quite Classical design in its symmetry and unity of effect. Coming to stone bridges, they had to consider several points — the form of the arch, the treatment of the spandrel, the treatment of the piers. Semicircular arches were out of the question in these days of wide spans; they had to choose between the elliptical and the segmental form. The former looked best, as it rose tangentially from the pier-surface, while the segmental arch was butted against it, and the elliptical arch gave more height close to the pier; on the other hand, it was flatter at the crown than a segmental arch of the same span, and for a large span required, therefore, very careful building. The voussoirs might either be treated on the same plane with the masonry of the haunches, as in London Bridge (which had a very fine solid effect), or they might be accentuated so as to leave a defined spandrel. Such a spandrel, however, should never be panelled, as at Grosvenor Bridge, Chester; that was a treatment for carpentry, not for masonry. The treatment of the soffit with groins, as in many mediæval bridges, was very effective for bridges on a moderate scale; but for bridges on a large scale there was perhaps nothing so fine as the sweep of the plain unbroken soffit. The projection of the piers, although there had been a kind of traditional notion since Renaissance times of decorating it with a columnar order, ought rather to be treated as a buttress. The raking lines of the balustrade and cornice should be stopped against the pier, not carried round it; the pier was a vertical abutment to them, and not any part of them. The old mediæval treatment of the buttresses as pointed to divide the current produced in itself a picturesque effect founded on practical requirements; but except in a tidal river this treatment should only be strongly accentuated on the up-stream face of the bridge. Character was given by thus suiting the build of the bridge to the run of the water, as was shown in the grand effect of the St. Lawrence Bridge, with its immense up-stream buttresses to break up the floating ice. Waterloo Bridge was an exceptional example in which the Classic cornice was excusably used, because the whole bridge was entirely level from end to end. In London Bridge, where there was a gradient, Rennie, with true instinct, discarded the cornice, and only used a small corbel table. The new Putney Bridge was a very good example, in the same school, of a granite bridge simply and plainly treated, with no adventitious ornament. Reference was then made to Blackfriars Bridge, and to the unfortunate design of the piers as stumpy granite columns of immense thickness, which could have carried a tower over them, and had nothing to carry but a balcony. These columns, like Alexander the Coppersmith, had "wrought us much evil," for engineers seemed to be so much enamored of the effect that the first design for the new Vauxhall Bridge was almost an exact imitation of Blackfriars Bridge. The Institute of Architects had begged for a granite bridge instead of a steel

one of this design; it was replied that the demands of the various authorities in regard to width of span and gradient rendered a granite arch impossible. Eventually a compromise had been come to by adopting a concrete arch with granite facings. The concrete arch itself was an admirable piece of construction on a somewhat novel principle; a section of it was shown and described; but in the so-called architectural treatment the influence of the Blackfriars stump-column still prevailed, and the pier was treated with an enormous half-round column which had nothing to carry but a lamp-standard, and this again had to be made far larger than necessary in order to appear to provide something for the column to carry. The whole thing was so completely out of scale that though the actual height was about 70 feet from the water-line to the top of the lamp-column, any architect would suppose from the scale of the drawing that it represented a structure about 30 feet high. Then a heavy cornice of supposed Classic style was used below the parapet and carried round the column on a raking line; an arrangement which could not be carried out except by "fudging" the mouldings at their mitre junctions; and another effect of this deep cornice was to leave so little depth for the centre voussoir as to make the centre part of the arch hopelessly weak in appearance. A design by the lecturer was shown in which, on the same constructional lines, the pier was treated in a buttress form; and by substituting for the heavy cornice a simple corbel table (as in London Bridge) a greater apparent depth was given to the central voussoirs, while the whole of the voussoirs were treated in a slightly decorative manner, by fluting each alternate one, so as to suggest the idea of their being what they actually were — a facing or *revêtement*, not an essential element in construction. Another design was shown for a different treatment of a pier, with the flat central buttress-member turned round at right angles to the line of the bridge, and carrying the lamps also at right angles to the bridge. This had a very bold effect, and there was something to be said for it in a practical sense. When he had exhibited this design in connection with a paper read a little while since before the Birmingham Architectural Association, one of his audience remarked that it was "Gothic feeling with Classic detail"; and that, in fact, was exactly what he was driving at, and suggested the moral with which he would conclude, viz, that if anything satisfactory was to be done in the architectural treatment of bridges, it would not be by plastering on to them architcetural details meant for quite different situations, but by returning to the mediæval principle of so designing the lines of the masonry as to make them in themselves expressive and characteristic.

"Mr. Aston Webb said he must ask them to pass a hearty vote of thanks to Mr. Statham for his lecture. He did not think there were many ladies or gentlemen in that room who would be likely to build a bridge — he felt sure he would not — and though ladies were becoming architects he did not think they would be asked just yet to put up bridges; but though it was unlikely they would be called upon to build a bridge, it was important that they should have some notion of how one should be built. It was also desirable that where there was a fine bridge — as there was in London and in many of our towns and country places — we should know how to value it and keep it. Mr. Statham had not only criticised the design of bridges which had been erected or were about to be erected, but he had shown them what, in his view — a view with which most of them would agree — were the lines on which bridges should be put up. There was hardly anything more poetical or romantic, he thought, than a bridge. The connecting of two banks by solid material and the passing of traffic over it, or the cross-traffic underneath on the water-way or roadway at right angles to the traffic over, always formed a subject of interest, and must impress even the most unreflective. He thought they would all agree with Mr. Statham that the interest which was connected with bridges was best obtained and preserved by the simple proportions of the bridge itself. We did not want to be distracted by little bits of ornament and misplaced construction, which was really not construction at all. It was not for him to go into a criticism of bridges which had been built or were about to be built, but, as to London Bridge, he endorsed Mr. Statham's remarks in regard to the necessity or not for widening that bridge. It might be a necessity, but whenever he had had occasion to cross the bridge his traffic had never been interfered with, and since the Tower Bridge had been erected he had been able to get across London Bridge with the greatest ease. But if the bridge must be widened — and he supposed they must accept the opinion of those in authority as to that — they were entitled to know what was going to be done, so that they might be in a position to know whether what was going to be done was the best thing to be done; and for this reason he thought the lecture had been of considerable use. One great difficulty in a stone bridge was that the arch, from its nature, was never at rest; it was always pressing out and, to some extent, upwards. Stability was obtained in a building with an arch by weighting it at the top, but that was a thing which, in large-span bridges, which now, of necessity, were constructed across great rivers like the Thames, was almost an impossibility, and a very narrow depth of masonry over the top of the arch must always give, to some extent, an idea of weakness, for there was nothing but a thin line of roadway for the arch to carry. He thought Mr. Statham was right in omitting the cornice in his design for Vauxhall Bridge and deepening the arch as much as possible. Much as we admired London Bridge and Waterloo Bridge, one had to give way — and we gladly gave way — to the French as the great bridge-designers of the day. The new bridge for the Paris Exhibition was acknowledged by all artists and all who were interested in such matters to be a magnificent bridge. We must hope that Vauxhall Bridge would be able in some way to vie with that bridge, but it was not for him to say whether it would or not.

"The lecture was illustrated by more than sixty lantern-slides of bridges of various kinds, arranged so as to successively illustrate the various points touched on in the course of the lecture."

BUILDING-LEGENDS.

UNLIKELY as it may seem at the first glance, there is much that is curious and legendary associated with the matter-of-fact art of building, and in the following lines we shall cite some of these legends and curiosities, which are to be found scattered up and down the country. Thus, it has been written of the spire of Chesterfield Church — which many consider wonderful, though, as a fact, it is only somewhat out of the perpendicular: —

> "Poor devil! poor spite,
> To make a spire a laughing-sight."

This rhyme refers to the perversity of the builder, who originally erected the church without a spire, but, being compelled to add one, made it crooked. One of the legends attributes the mischief to the Prince of Darkness, who one day, being fatigued, folded his wings and rested on the steeple. Some of the incense which was being wafted in the aisles below escaped from the church, crept up the steeple, and tickled the arch-fiend's nose to such purpose that he gave a terrific sneeze, and so dislocated the steeple that it has been twisted ever since! Another tale in connection with this church is that on the occasion of a wedding party passing into the building the steeple bowed to the bride and bridegroom, and has remained crooked ever since. The same tradition attaches to an old church in Lancashire, of which it is said: —

> "The church at Little Winwick,
> It stands upon a sod;
> And when a maid gets married there
> The steeple gives a nod.
>
> "Alas! how many ages
> Their rapid flight have flown.
> Since on that high and lofty spire
> There's moved a single stone."

It is a legend, dating from mediæval, if not earlier, times, that, in the erection of cathedrals and other edifices devoted to ecclesiastical uses, the Prince of Darkness always claimed one human life as a sacrifice during the process of building, and, as if in confirmation of this gruesome legend, there is hardly a cathedral or minster in the world which has not some such story associated with it. For instance, at Shottesbroke, in Berkshire, the tale runs that when the capstone was being fixed on the spire the architect called for wine with which to drink the health of the King, and that after partaking thereof he fell down and was killed. Possibly the wine was drugged, or was very potent. A coffin-shaped stone in the churchyard, bearing the letters, "O! O!" — his exclamation as he fell — is said to mark the spot where he lies buried. The legend of St. Francis of Assisi, who rescued a poor mason from falling, and that associated with Sir James Thornhill's painting in the dome of St. Paul's Cathedral, are too well known to call for recapitulation here.

Many churches have legends associated with them, and generally in reference to some action of a former parson. Thus, the following three jingles, relating to bells, are self-explanatory: —

> "Arlesey, Arlesey, wicked people,
> Sold their bells to build a steeple."
>
> "Owesby parish, wicked people,
> Sold their bells to Kelsey to build a steeple."
>
> "A very fine trick of the Newington people,
> To sell the bells to build a steeple."

Of Berwick, in Sussex, the local rhyme runs: —

> "The parson was poor and so were the people,
> So they sold the bells to repair the steeple."

And it is a fact that only one now remains out of four bells there in 1724. At Mevagissy, in Cornwall, the natives have the following rhyme: —

> "Ye men of Porthilly,
> Why were ye so silly,
> In having so little power?
> Ye sold every bell,
> As Govan men tell,
> For money to pull down your tower."

— *London Standard.*

BURMESE BELLS. — One of the odd things the visitor to Burmah will notice is the large number of bells about the pagodas. These bells are usually hung on sacred posts a few feet above the ground. They are sweet-toned, as all Burmese bells are, but they are not furnished with tongues. The worshipper who comes to pray before the pagoda strikes one of these bells with a wooden mallet. This is to attract the attention of the god. — *Boston Transcript.*

NOTES AND CLIPPINGS

STATUES IN THE PARIS STREETS. — It is not the Londoner only who grumbles at the lack of beauty in the statues adorning the streets and squares of his city. The Frenchman just now makes a point of grumbling quite as loudly at the "almost unanimous" ugliness of the modern statues "encumbering" Paris. These statues, says the outspoken *Journal des Débats*, are not so much erected in honor of one dead man as for the glorification of several living ones, who form the "Commission" for the erection of a statue, and receive decorations for their endeavors. A famous French sculptor is quoted in this connection, who had sent in his design for a statue of Pasteur. He had suggested the genius of the great scientist by symbols, but the commission would have none of them. "Your work," they said, "is fine, but it is incomplete. What about the diseases of silk worms, the manufacture of vinegar and of beer and *vin*, about cholera in fowls?" And nothing the artist could say as to the impossibility of reproducing sick silkworms and cholera-ridden roosters on a monument could move the commission. Under such conditions, it is small wonder Paris statues are no better than they should be. — *Westminster Gazette*.

OBITUARY. — William Reynolds Snead, President of the Snead & Co. Iron Works, of Jersey City, N. J., manufacturers of structural and ornamental iron-work for buildings, died suddenly in New York City, on Thursday, March 27, 1902. He was forty-one years of age, having spent his time in the business since his graduation from the Massachusetts Institute of Technology, Class of 1881. The Snead Works were pioneers in the use of iron for architectural purposes, and were founded by Charles S. Snead, Sr., in Louisville, Ky., in 1848. They were successfully operated in that city for fifty years. A fire in 1898 destroyed the plant and they were transplanted to Jersey City by the deceased, William R. Snead, where they are in successful operation. Mr. Snead had just begun to realize some rest from the hard work of building and installing and organizing a new plant in a new place when he met his untimely death. He was master of his business and had a large circle of friends. His father, Charles S. Snead, Sr., the founder of the business, is now enjoying a hale old age in his eighty-third year, having retired from active business.

TO JUDGE A RIVER'S BREADTH. — It is necessary to make use only of the eyes and the brim of a hat to measure the width of any ordinary stream, or even of a good-sized river, and here is the way to do it: Select a part of the river bank where the grounds run back level, and, standing at the water's edge, fix your eyes on the opposite bank. Now, move your hat down over your brow until the edge of the brim is exactly on a line with the water-line on the other side. This will give you a visual angle that may be used on any level surface, and if, as has been suggested, the ground on your side of the river be flat, you may "lay off" a corresponding distance on it. To do this you have only to hold your head perfectly steady, after getting the angle with your hat brim, supporting your chin with your hand, if necessary, and turn slowly around until your back is towards the river. Now, take careful note of where your hat brim cuts the level surface of the ground as you look over the latter, and from where you stand to that point will be the width of the river — a distance that may readily be measured by stepping. If you are careful in all these details you can come within a few feet of the river's width. — *Detroit Free Press*.

A COLLECTION OF TAVERN SIGNS. — The April exhibition at the Guildhall is to be of French and English painters of the eighteenth century, and one feature of it should be particularly interesting to our readers who contributed so many instances of curious tavern signs. For a collection of signboards is to be made, and already French collectors are being asked for specimens of Chardin, Lemoynes, Nicholas Watteau, and other famous artists who paid their tavern scores with their brush. This method of payment has been common enough with young or struggling artists. The late T. Sidney Cooper painted his way to Brussels; the Royal Oak at Bettws-y-Coed has a signboard done by David Cox, and there are few of the old-fashioned inns on the Thames which cannot show pictures which were paid for in kind. — *London Chronicle*.

A MALLEABLE-GLASS PROCESS. — Louis Kauffield, says a despatch to the Boston *Transcript*, a glass manufacturer of Matthews, Delaware County, after experiments covering two years, announces that he has discovered the method of making malleable glass, long considered one of the lost arts. The manufactured product is not sensitive to sudden changes of heat and cold and may be moulded very much after the manner of iron. Kauffield says he has dipped almost red-hot lamp-chimneys of the new glass in water that was icy cold and they were not affected. The new process promises the making of cooking-vessels out of glass, and the use of glass in stoves. Mr. Kauffield also believes that he can weld the glass together. Manufacturers who have seen the Kauffield experiments speak highly of them.

HOW THE NEW-YORK SUBWAY WILL CROSS THE HARLEM RIVER. — But one other interesting feature of the work of construction need be described — the building of the tunnel across the Harlem River. Here a problem of selection was presented which for a time puzzled the engineers. More than thirty different plans, any of them feasible, were suggested. In the end, the one which at first sight would seem the most difficult was decided upon. Two lines of sheathing were driven into the bottom of the river at a distance apart equal to the width of the channel. The planks were placed close together, so that when the wood swelled by the action of the water, the joints became practically water-tight. A platform, called the "roof," was then rested on top of the sheathing, and a third wall, at right angles, and touching the ends of the first two walls, completed a box, which, when pumped dry, allowed the men to descend and dig out the bottom of the river. As the sub-river soil was removed it became necessary to load down the roof of the box with weights in order to prevent the sheathing from floating. But half the width of the stream could, of course, be thus worked at a time, as navigation had to be kept open by the other half. — *Pearson's Magazine for April*.

ELECTRICITY AT ST. PAUL'S. — On Easter Sunday last, St. Paul's, in London, was, for the first time, radiant with the electric-light. It is three years since the change was decided upon, and ever since the work of preparation has been going on. Miles and miles of wire have been taken into the crypt, and carried up in galvanized pipes, through the shafts in the walls which bring the rainwater ducts from the roof, to the various points where the wire is required to enter the building. The supply is taken from the Charing Cross and the City of London companies, so as to guard against a possibility of failure. The complete scheme of lighting requires about two thousand glow-lamps, but owing to the expense only part of the work is done at present. The ring of gas-jets around the "whispering gallery" at the base of the dome is left, as to replace them would need six hundred lamps. The wiring has been completed, and there only remains the introduction of the standards and pendants in the cathedral, which will be of ornamental brass, partly furnished by conversion of the existing gas fittings. The work is being carried out under the supervision of Mr. Harding, clerk of the works of the cathedral. Naturally, the adaptation of electric-lighting to such a building as this great metropolitan cathedral, a work for which no precedent exists, has given ground for the utmost variety of opinion. Seven years ago an experiment was made in lighting St. Paul's with arc-lamps. At dead of night, that the public might suspect nothing of the startling innovation proposed, the Dean and Chapter stole silently on tip-toe into the building, and after some delay the great moon-shaped lamps suddenly blazed forth. A single trial was sufficient to condemn the arc-lamps, but even with glow-lamps there are many ways of lighting a cathedral. First of all, there is the architectural way, by which the outlines of arch and frieze and spandrel are marked by lines of lamps. This has the advantage of being the cheapest system, for the lamps can be attached direct to the cable, and no pendants or standards are required. It also shows the form and proportion of the building, in what many consider a pleasing way, but the cathedral authorities did not think the plan worthy of St. Paul's. Then there is what may be called theatrical church-lighting, in which concealed lamps throw a bright illumination upon some central point or figure. The altar of St. Alban's, Holborn, is illuminated by hidden lamps in this way, and some popular American preachers during their sermons have the lights turned low and a lime-light directed towards the pulpit, causing the congregation to see them enveloped in a sort of saintly radiance. At St. Paul's itself, when the new reredos was erected screened gas-lights were at first employed to illuminate it, but the plan was abandoned as not in the best taste. One other use of the electric-light in church we may describe as the "ecclesiastical." It is to be seen at St. Saviour's, Southwark, where imitation candles made of china have tiny glow-lamps, in place of flame. This form of altar-decoration has been rejected at St. Paul's as meretricious and gaudy, and the lights are arranged purely for congregational use. They are therefore placed — whether erected on standards or suspended from above — as nearly as possible in a plane, about 15 feet above the floor. For reading this will give the maximum effect, and although the richly-carved marble and sparkling gold incrustations of the upper part of the cathedral will not be in the most brilliant light, they will be seen as well as by the gas heretofore used. — *Boston Transcript*.

NOTES AND CLIPPINGS. 23

WE are very glad to receive from the Municipal Art Society of New York an official statement of the plan which has been drawn up by its committee on the proposed exhibit of a model city at the St. Louis Exposition of next year. This plan, which is founded on one prepared three years ago by Mr. William S. Crandall, as secretary of the Exhibition Committee, and submitted to the management of the Buffalo Exposition, but not carried out, from lack of funds, is far more comprehensive than the schemes published in the newspapers and magazines, including even an exhibit of the methods for securing uniformity in municipal accounts which have, of late, engaged the attention of reformers, as well as one of a model health department, introducing, for example, the sterilized-milk stations maintained by the municipality in Rochester, N. Y., and in New York City by private benevolence, by which the mortality among infants has been greatly reduced. These features, although not architectural, are quite as essential to a well-organized city as asphalt pavements or well-designed park railings; and it is very much to the credit of the Municipal Art Society and its representative that this fact should have been recognized. While the profession, naturally, interests itself more in the artistic features of a city, people generally will be more attracted by the novelties in sanitation, transportation, lighting and sewage-disposal which the Society includes in its programme, and the people who come to look at the sewage-irrigation model, or the vestibuled electric-cars, or the acetylene street-lamps, will finish their visit by an inspection of the artistic signboards and æsthetic bridges, which they would never have looked at by themselves.

IT seems to us that, with proper management, a comprehensive scheme of the sort proposed by the Municipal Art Society might be made the most valuable and conspicuous feature of the Louisiana Purchase Exposition. In Paris, in 1900, a great deal of attention was attracted by the scattered elements of what would, under this scheme, be advantageously collected and systematized. In one series of rooms at Paris, for example, was a collection of plans, models and pictures of hospitals and asylums, which offered great interest. Some of the Russian hospitals were shown by means of miniature buildings, the roof of which opened like a lid, showing the little beds, with the tiny patients, half an inch long, in the wards; many other establishments were represented by models in relief of the buildings and grounds; and, in general, great efforts were made to have the exhibits as realistic as possible. So, in the school department, rooms of the actual size were shown, the Russians, who were conspicuous in all these branches, presenting, for example, a village library complete, including all the fittings and furniture, even to the books on the shelves. In another building, at some distance, was an exhibit, with real babies, of the "couveuses d'enfants," or establishments for bringing up sickly or prematurely-born infants by keeping them in a uniform temperature, in plate-glass cases, which have been found so valuable in France; and in other portions of the Exposition grounds, even as far as Vincennes, were scattered extremely interesting examples of municipal utilities of various kinds. The plan of the Municipal Art Society, to show these things together, as they actually occur, would add greatly, not only to the convenience of studying them, but to the interest of each, and we earnestly hope that it may be found practicable to carry it out.

THE new methods of government in New York have begun to be applied to the theatres. Every architect knows that the building-laws concerning theatres in New York are very strict, and are, on the whole, very judiciously drawn up; but a circumstance less generally known is that, in the case of many new theatres, not the smallest pretence of obeying them has been made. According to evidence collected by the new municipal officials, a considerable proportion of the newest theatres, instead of being practically fireproof, as the law requires, are fire-traps of the most dangerous description, the safeguards demanded by the statute having been deliberately omitted, apparently with the acquiescence of the inspectors. It is gratifying to learn that a list of the deficient theatres is in course of preparation, and their proprietors will be presented with the alternative of remodelling their buildings in such a way as to bring them into conformity with the law, or having them permanently closed. Another police regulation of great importance, which absolutely prohibits the placing of seats in the aisles or passageways of any theatre, hall, church or other place of public assemblage, is also constantly violated in theatres of a certain class. Until now, the proprietors of these theatres, presumably in consequence of a private understanding with the police authorities, have escaped punishment; but warnings have now been issued that the law will be enforced, and New York theatres will have their aisles cleared of seats, or their proprietors will go to prison. It is hardly necessary to point out that, in case of fire in a theatre, obstructions in the aisles may easily cause the death of multitudes of people. All persons who go much to the theatre should bear constantly in mind the fact, proved by many examples, that the average time which elapses between the appearance of fire in the auditorium of a theatre, and the death of every person remaining in it, is less than three minutes. In other words, any person who does not get out of a theatre in less than three minutes after fire makes its appearance will never get out alive, and the obstruction of the passageways by seats simply ensures the death, in case of fire, of all the people in the front portion of the house.

A NEW inconvenience has been found to attend the construction of high buildings. In New York, last week, the inhabitants of a house on Fifth Avenue were disagreeably surprised to have a block of granite, weighing seven hundred pounds, let fall from the sixteenth story of a hotel in process of erection next door, come through the skylight over the main staircase, and continuing to descend, accompanied by a shower of broken glass, demolish two stories of the richly-carved staircase, and finally land on the hall floor, after doing damage to the extent, as the owner estimates, of ten thousand dollars, without including the annoyance to the inmates of the house, who, their staircase being destroyed, were obliged to use the fire-escape to go to and from their bedrooms. Almost on the same day six beams, which were being hoisted to the fourth story of another new building on Fifth Avenue, dropped from the chain which held them upon the roof of a picture-gallery next door, two of them breaking through the skylight, and falling to the floor. About thirty people were in the gallery at the time, but, fortunately, no one was injured.

LA CONSTRUCTION MODERNE calls attention again to the danger to which the precious collections of the Louvre are exposed through the installation in the building of the Ministry of the Colonies. It is now nearly twenty years since the French Government, by a formal decree, ordered that all the buildings of the Louvre, without exception, should be devoted to the purposes of the museum which bears the name of the palace. The ink was hardly dry on the decree when a portion of the palace was taken, "temporarily," for the accommodation of the Ministry of the Colonies. In accordance, apparently, with the "temporary" purpose of the installation, the

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

changes made in the building were of the flimsiest and most dangerous character. At the very outset, one hundred and sixty-five small offices, with the incidental corridors and passage-ways, were made by dividing the great rooms of the palace by partitions of spruce boards, and stretching above them ceilings of cheap thin cloth. This was a tolerably incautious proceeding on the part of people whom American architects are continually reviled for not imitating; and the subdivision has since been carried still farther, in the same style. As M. Planat says, the whole affair would burn up "in the wink of an eye," if it once took fire, and the officials of the Ministry of Colonies are so impressed with the danger to themselves and their subordinates which the construction presents that they have caused placards to be posted among the offices, giving directions where to run for safety at the first alarm; yet, in spite of the obvious and imminent risk which the installation involves to the remainder of the building, which, it must be remembered, has floors throughout of wooden beams, covered with waxed boards, and lofty mansard roofs, all framed with wood, and covered with boarding, sheet-lead and glass, and the certainty that even a small fire in the galleries would effectually ruin the priceless treasures of art which they contain, this "temporary" installation has been allowed to remain for nearly twenty years, and there is still no sign of its removal. Another circumstance which makes the invasion by official intruders of the premises declared by law to be entirely reserved for the national museum is that the offices of the Ministry of the Colonies occupy room which is urgently needed for the display of objects which belong to the museum, but cannot be shown, for lack of space in which to display them. For example, a magnificent collection of French paintings of the last century, valued at several millions, was recently bequeathed to the Louvre by M. Thomy-Thiéry, of the island of Mauritius; while a fine collection of Greek and Roman antiquities, belonging to a noted amateur, M. de Clercq, has also been bequeathed either to the Louvre or the Cabinet des Médailles, preference being given to the Louvre. Neither of these rich collections can be shown, and the De Clercq collection may be lost in consequence; and the officials of the museum report also that it has been impossible to place before the public the magnificent collection of drawings by old masters which it possesses, on account of the impossibility of finding room to show them. It is hardly necessary to say that the preservation of the Louvre and its contents, and the proper display of the artistic riches which it possesses, are matters which concern the whole civilized world; and nothing, perhaps, would give pleasure and relief to so great a number of persons as the announcement that the Ministry of Colonies had departed, with all its furniture and paraphernalia, from the building which is generally recognized as the very centre of art.

PERHAPS the most important field for archæological exploration that the world now affords is to be found in Yucatan. Although Central American antiquities do not appeal to average people, who are more interested in Romulus and Numa Pompilius, or Achilles and Priam, or Theseus and Ariadne, and the times in which these personages lived, than in the subjects of the undecipherable hieroglyphics of Copan, men of real science are inclined to believe that there was, in times more ancient, perhaps, than those of which even the Assyrian and Cretan records give us knowledge, a mysterious connection between Central America and Asia, if not, as there seems to be some reason for supposing, between Central America and Egypt. It is unlikely that any of the existing ruins in Yucatan date back to the period of such connection, but the inscriptions with which they are covered may, when they are deciphered, refer to traditions of extreme importance to the history of the human race. In this part of the world, moreover, archæological explorers enjoy an advantage which is hardly found in any other, that the present inhabitants are, so far as is known, the direct descendants of those who occupied the country, perhaps, ten thousand years ago. While nearly every other region of archæological interest has been conquered and occupied by a succession of different races, the Mayas have, so far as we know, never been driven from their homes by strangers, or compelled to submit to foreign innovations. They have the advantage, also, of being ignorant enough to have no literature, and hardly even a written language, and their traditions are, on that account, much more likely to have been kept pure. When the inscriptions on their ancient monuments are read, and compared with the verbal traditions collected by some one as familiar with the Mayas, and as thoroughly in their confidence, as the lamented Cushing was with the Zuñis, it is, perhaps, not too much to expect an archæological sensation comparable with that which followed Rawlinson's discovery of the key to the cuneiform writing.

ANOTHER dust explosion in a coal-mine in Tennessee has added twenty-two victims to the long list of those who have been sacrificed to the carelessness or ignorance of people who ought to know better in regard to the explosive character of an atmosphere charged with inflammable dust. In this particular mine it is customary to spend the earlier part of the day in drilling holes for blasting, and, toward the end of the afternoon, the miners charge the drill-holes, adjust the fuses, and make their way to the open air, leaving two men, whose duty it is to light the fuses. The mine seems to be carefully operated, for the men are required to carry safety lamps, and the two "firemen" are under orders to wait until the others are in safety before lighting the fuses. It is probable that in the present instance the firemen were in a hurry to get home, and thought, as usually happens, that there was no harm in stretching their instructions, if nobody was near to see them, for, in a few minutes after the time for the other miners to leave work, and while they were still coming out of the mine, a terrific explosion took place, tearing to pieces the building over the mouth of the mine, killing some men who stood near, and, of course, annihilating all those who were in the mine, or on their way out of it. A certain amount of "firedamp" occurs in the mine, and may have contributed to the explosion, but it seems most probable that a blast, badly tamped, or unskilfully proportioned, blew out of the drill-hole, setting fire to the explosive mixture of coal-dust and air which filled the mine. Several similar accidents have taken place in the same and neighboring mines within a few years. As our readers know, explosions of this sort often occur in saw-mills, flour-mills, cotton-mills and other places where the air is filled with fine dust, but the exact nature of the explosive action, and the conditions on which it depends, have been very little studied. In saw-mills and flour-mills it is now usual to draw off the dust by means of ventilating-fans, but anything of this sort would hardly be practicable in coal-mines, and the problem of removing the dust in such places, or of keeping it from exploding, still awaits solution.

A FEW years from now some one, we hope, will write a history of the natural-gas industries in this country. For two years or so the flow of natural gas from the wells has been diminishing, so that, instead of an almost uncontrollable pressure, often amounting to three or four hundred pounds to the square inch, the disposition of the gas to escape has become so languid that, in many cases, it must now be sucked out of the wells by air-pumps, and forced into the distribution mains, while, in others, not even this process suffices to secure a supply. The manufacturers who used the natural gas have been the worst sufferers by the failure of the supply; but the makers of plate-glass, who were able, as long as the gas lasted, to produce a beautifully clear and uniform material, have taken advantage of their experience to establish apparatus for manufacturing coal-gas, which is forced into the mains designed for natural gas, and will, undoubtedly be quite as effective in maintaining the clearness of the product, while it will have the advantage of being more uniform, and more reliable in quantity. In some of the Indiana towns in the gas-district, the owners of private houses are arranging to combine for the purpose of making artificial gas, with which to feed the furnaces and fireplaces once supplied with natural gas, and the example will, undoubtedly, be widely followed. It may be suggested that the agents of the Mond process in this country might, perhaps, do worse than establish themselves in Pittsburgh, Buffalo and Indianapolis, and arrange on a large scale for replacing the natural gas with the Mond gas, properly enriched. The main expense of the installation, that of furnishing and laying the mains and service-pipes, is already paid, and the Mond Company could probably secure the use of them on very favorable terms from the owners, who, having no longer natural gas to send through them, must either abandon them, or dig them up and sell them for old iron. In England, the Mond Company can furnish and lay its own pipes, and sell gas for about ten cents per thousand feet; so that, with the use of mains and service-pipes at a nominal expense, it should be possible to furnish the same gas here at rates very little, if at all, higher than those paid for the natural gas.

THE UNKNOWN BERNINI.

EVERY one knows that Lorenzo Bernini, at once architect and sculptor, as the favorite of Urban VIII and his successors in the papal chair, had at Rome during the seventeenth century a princely standing. Everybody knows, likewise, that Bernini, especially in his last years, became the greatest artist of his time, that the piazza of St. Peter's, his architectural *chef d'œuvre*, is one of the grandest architectural ensembles in the world, and also that his sculptural work is very ostentatious, and that which most closely rivals the sculpture of Michael Angelo; but, perhaps some of my readers will be surprised to learn that Bernini, artist in all kinds, like Orcagna and Leonardo, was an adept in caricature, a dramatic author, and himself prepared theatrical decorations, being greatly interested also in the machinery of theatres. If the fancy for Barocco art had not sprung up during these latter years in Italy, and had not the advanced spirits of the time given themselves over to the consideration of every kind of art movement, assuredly this new and curious side of Bernini's character would have remained for a long time unknown; for the favorite of Urban VIII did not arouse the interest of artists and students until our own day, and it is to a student of Bernini that we owe these new facts concerning the unknown side of the artistic life of the subject. Already, to tell the truth, Baldinucci, in a biography of Bernini which he wrote, had pointed out that the master did practise caricature; but the mere words of Baldinucci made no particular impression, and if chance had not led to the discovery of the Berninese caricatures, no one, in all probability, would have given any heed to what Baldinucci wrote. He said, apropos of Bernini, after having praised the extraordinary freshness of the drawing of the human figure in his "Hero": "The effect of this frankness has been that he labored singularly in that kind of drawing which we call caricature, where the pen-stroke which burlesques the image of another still preserves the resemblance and even the majesty, if sometimes the caricatures were those of princes, as happened frequently enough." We know from another source that a certain quantity of caricatures flowing from Bernini's pen were found in the Galleria di San Pastore, in the villa of Terra di Gallicano, inhabited by the Dominican Fathers, to whom the master had given them. It is also important to remark that these caricatures were sent to princes, in homage and as testimony to the intellectual activity of Bernini. In fact, Signor Fraschetti discovered lately a letter, dated 1652 at the Court of Este, in which there is question of two caricatures by Bernini, one representing the Cardinal Trivulzio and the other a certain Giaconazzi, a servant of Cardinal Pamphily's. In this letter, by a certain Francesco Gualengo, it is said that the latter sends to His Most Serene Highness two caricatures, in the knowledge that everything which comes from the hands of the eminent artist is accepted with pleasure by His Majesty.

The discovery of the caricatures of Bernini, some of which I here reproduce in support of this letter, has been purely accidental. Of late, they were rearranging the engravings and drawings in the Corsiniana Collection, and this led to a more attentive study of these drawings, and to the conclusion that the caricatures in question were the work of Bernini. It is perfectly true that they are not signed, but all the connoisseurs, supported by arguments whose probability I for my part admit, in face of these caricatures in the Corsiniana can think only of the name of Bernini.

Almost all of the caricatures are accompanied by inscriptions which help in the identification of the subjects.

No. 1 bears a legend, in Italian, of course: "A French Chevalier." It represents a sufficiently aristocratic type, perhaps sketched by Bernini during his sojourn in France at the time he was preparing his design for the façade of the Louvre. A very curious feature, apart from the elephantine nose, is the suppression of the eye. Perhaps, in this chevalier, the eyebrows wholly eclipsed the little eyes. No. 2, likewise, has its legend: A captain of the "Company of the Romanesques," throwers of stone (*sassaioli*) in the wars of Urban VIII. For a long time Rome was famous for its stone-fights between groups of people who inhabited different quarters of the city, and sometimes these street-fights resulted in death and great grief to many families of the great city. Bernini, in his caricature of the Captain, has admirably expressed one of the types of the Roman populace, a type which we still meet to-day in the city streets — curious-looking creatures with long necks and very small eyes which seem to be aiming at an enemy at the very moment of attack. No. 3 is that of a Venetian advocate, a laughable type of a man, quiet, and content with the joys of life. No. 4 carries a legend, and is recognized as the caricature of Cardinal Antonio Barberini, born in 1607, an empty-headed but superb man, whose whole value consisted in his being the nephew of Urban VIII. No. 5, beside it, represents the Cardinal Chigi when he was a young man. This Chigi is Fabio Chigi who became pope in 1655, under the name of Alexander VII. The last of the series represents the head coachman of the Infantado of Spain, a sufficiently vulgar type, with frowning eyes and neglected hair. Unquestionably, the caricature is more interesting than the original could have been. I won't waste time over the other caricatures, which anybody can see at Rome in the cabinet of engravings in the National Gallery. The sketches which I have given are more than sufficient to show the style of Bernini as a caricaturist.

Now we must recognize the architect of the Piazza of St. Peter's as a dramatic author and an inventor of theatrical decorations, according to the revelations of Signor Fraschetti. In the first place, we must know that comedies, melodramas, tragedies and other productions of the kind held, during the first half of the seventeenth century, a place of great favor in the city of the popes. Foreigners came to Rome to be present at theatrical representations which sometimes were very loose in their morality, and enthusiasm over these representations reached such a point that, in 1644, the French, as a mark of their pleasure, erected a theatre on the Piazza Navona, and there gave shows for the people. We know that the comedies most in vogue at Rome were those which abounded in *bons mots*, which were aimed particularly at personages about the Court.

Amongst the comedies composed by Bernini, a memory of one in particular is preserved; namely, that entitled "The Inundation of the Tiber," apropos of which we read, in documents drawn from the archives of Modena, dated February 16, 1638, the following words: "The Chevalier Bernini, Monday evening, presented a marvellous comedy, and absolutely there were three scenes which struck everybody with wonder." According to the account given of this comedy, it appears that the author secured his effects by stupefying theatrical *coups* and by the vivacity of his dialogue. If we follow the documents of the times, we find that one of the spectators wrote these words:

"I have been to Bernini's comedy [it is still a question of the 'Inundation of the Tiber'] and, to tell the truth, it must be confessed that only he knows how to compose works like this, not so much for the quality of his machinery as for the manner in which the recitations are given. There was an inundation of the Tiber and a fall of

a house with three persons in it, two feigning death and one pulled out half dead, and all the three carried across the stage with a feeling for art of the highest character, and with equal naturalness; but one in particular, the wounded one, smashed almost to pieces in every part of his body (and surely this was very artfully carried out), both amused and terrified us. At the end, the scene opened and there appeared a perspective of extreme beauty at the back of the theatre. This represented a comedy and the players, and, at a considerable distance, many spectators, partly painted, and part moving to join them, some on foot and some a-horseback, some in carriages and some in litters."

In another account by a spectator we read that even Bernini played a rôle. He was arrayed in the costume of an old Florentine, and took part in two scenes, in each without attempting to make Florence appear greater than Rome, he representing the most commonplace habits of the Florentines. The writer concludes his tale by saying that "the comedy was full of pleasantries and masterly strokes, but, nevertheless, more disguised than was usual, Bernini having named nobody, but always relying on general terms which were far from giving offence."

Documents also announce the existence of another famous comedy, "The Comedy of the Two Theatres," by Bernini, played at the carnival of 1637, and, from investigation, it appears that, two years before, Bernini had a satirical comedy played, in which he presented on the stage an ox, to satirize a Borgia, whom the pope had called an "ox in armor."

Bernini, besides his "Two Theatres" and the "Inundation," also produced other comedies more or less meritorious and spectacular. We mention "The Fair" and "The Sea," in which the artist produced the illusion of sunrise, and succeeded by the use of admirable engines. We will also mention "The Palace of Atlas and Astolphus," and the "Means of paying homage to the ladies in comedy." Bernini's importance as a dramatic author consists in this, that he, as they say, was the first to introduce at the theatre the grand spectacular comedies. The imagination and the talent of the author served him admirably in these representations.

It is for this reason, perhaps, that the dramatic artist also became a painter of theatre decorations. That Bernini practised painting everybody knows, but that the master ever placed his brush at the service of the theatre is less known to my readers. At any rate, it is incontestable that Bernini, having introduced, or enlarged, the frame of comedies so as to involve stage machinery, gave himself up to the painting of the decorations, just as in Italy before him certain painters, for instance, Andrea Del Sarto, Baldassarre Peruzzi, Raphael, Tribolo and others had done the same thing from time to time. In this connection, an interesting bit of testimony of the time is one that I found in documents bearing date of 1634. We read that, "In January, 1634, there arrived at Rome a brother of the King of Poland, the Prince Alexander Charles, in whose honor Cardinal Antonio Barberino caused to be reproduced the 'History of Saint Alexis' by the ablest musicians, with marvellous decorations invented by Bernini, which were changed several times, causing to appear palaces, gardens, forests, hell, and angels who, while speaking, actually flew; and at the end there was shown a large cloud which opened and brought to view the glory of Paradise."

Bernini amused himself and amused the people by painting caricatures amidst these decorations, and on the curtain of the Roman theatre he introduced caricatures of the Marquis Biscia which caused the very select audience to be convulsed with laughter.

It is a pity that time has exercised its pitiless work upon these productions of the unknown Bernini from which I have just lifted the curtain. To tell the truth, as a painter Bernini is an artist of mediocre merit, and even less than mediocre. Facts bear proof that he did not consider himself a painter, but with his own hands destroyed several of his canvases, and the altar-piece in the Vatican Gallery of Mosaics, painted by him, one of the rarest paintings which is preserved of the master, — attributed, by the way, also to Carlo Pellegrini, — does not belie the judgment which the world has passed on Bernini as a painter. Nevertheless, theatrical decorations demanded more imagination than altar-pieces, and all these decorations, full of spectacular architecture, trees, fruits, flowers, might have attained unheard-of effects, seeing that they proceeded from an artist as marvellously endowed as Bernini in all that concerns decorative pomp and the brilliancy of moving effects. ALFREDO MELANI.

MORE VAGARIES OF UNIONISM. — A few weeks ago, some painters who were redecorating the interior of a church in an English town ceased work because women were employed to clean the droppings of paint on the pews, and the employers had to finish the job themselves. And quite recently in a seaside town there was a strike of teamsters, because their employer refused to discharge a driver who had made a journey to a neighboring town three hours quicker than they themselves had been accustomed to take. — *Exchange.*

A PLEA FOR WOMEN PRACTISING ARCHITECTURE.[1]

I APPEAR before you to-night with a certain amount of diffidence, as the subject under discussion is not of my own choosing, and I fear I cannot do it justice. The title, to start with, is somewhat misleading. The dictionary says "plea" means a lame excuse or apology. Now, I do not propose to offer any lame excuses or apologies, all of which would be unnecessary under the circumstances. I shall merely bring to your notice some facts relative to woman and architecture, with most of which you are, doubtless, already familiar. Then, again, the title seems to suggest that I am conscious of a feeling against women architects, and, since I read the paper before your Association, it further implies that I believe such hostility is to be found amongst your ranks. Now, I wish it to be clearly understood that I disclaim both of these assumptions. Doubtless your committee had their thoughts directed to the choice of this subject by the knowledge of the existence of this feeling; but, personally, I have never met it. No one has ever maintained before me that a woman should not practise as an architect, and, if this view is held, I venture to think it can only be held by those outside the profession, who are consequently not acquainted with the functions, powers and responsibilities of an architect.

Since you are members of the profession, it seems superfluous to address you on the subject, as you must know better than any one what are the qualifications necessary for the exercise of the same, and therefore know better than any one that it is not a case of man or woman being best fitted to practise this art, but that it is entirely a case of personal capacity.

In a back number of the *British Architect* I came across the following remark: "Whether women, as a whole, are fitted to take up the profession of architecture we hold somewhat strong and, it may be, conservative views — views which we do not think it would serve any useful purpose to discuss." I hope very much that some one present holds similar strong and conservative views, and that he will be kind enough to express them to-night, as I may tell you the subject was selected by your committee as being a peculiarly useful and suitable one.

It would be a bold man who would assert that "women, as a whole," are fitted to take up the profession, considering so few women have turned their thoughts in this direction; but it would be a still bolder man who would assert that men, as a whole, are fitted to take up the profession, *vide* the enormities that are daily committed by men in the name of architecture. I repeat, it is not a case of men *versus* women; it is a case of individual capability and aptitude.

However, there are some people, we are given to understand, who maintain that woman, *per se*, is unsuited for practising our art. Wherein the weak point lies we shall, no doubt, discover in the course of the evening; but as far as I can judge, it lies outside the woman, and is not a defect inherent in her. I suppose the reason why woman should not practise architecture is because, except in one or two isolated cases, she has not practised it hitherto; and this is no reason at all.

The same objection is brought forward every time that women have attempted to enlarge their sphere of action, and yet yearly new proofs are given that intellectually women can, at least in many cases, hold their own with men. The results of university examinations show it; members of the medical profession testify to it; the legal profession numbers women in its ranks, both in France and in America, though up till now in England women have only been allowed to study for, but not to practise at, the Bar. "Let them study by all means," the conservatives say, "but draw the line at practice." And what is the use of instruction, I ask you, if it is to be turned to no purpose? What is study without an object? Knowledge without application? It is simply creating wants without granting the power of satisfying them. Living is not learning, but applying what one has learned.

If, then, it is granted that woman is intellectually capable of wrestling with the problems of architecture, are we to suppose that she is physically incapable of carrying on the work entailed? It were unreasonable to say her strength is not equal to the task when we see what women actually do in this country. Take chain-makers, for instance. Hundreds of women are employed in the very heavy work of chain-making, a most arduous trade, and you must remember how two or three years ago certain philanthropists were anxious that legislation should put a stop to this, as they asserted the work was too great a strain for a woman. This intervention only resulted in the Home Secretary being besieged by indignant deputations of these same women, all protesting their competence and defiantly baring their muscular arms as evidence of the strength on which they prided themselves. Then, again, our agricultural laborers are not, by a long way, all men. In harvest-time, when the work requires to be got through with all speed, women are called upon to labor side by side with their husbands and brothers; they toil from earliest dawn to latest twilight, through all the burning heat of the early autumn day, and so far from succumbing to this exposure, they weather it with the best of the men and live to seventy and eighty years of age. Now the bodily fatigue an architect must be prepared to undergo cannot be compared to the physical strain our women endure when employed as field-farers or as chain-makers.

I do not mean to make light of the arduousness of the profession. The mere study of architecture involves a great deal of physical as

[1] A paper read by Miss Ethel M. Charles, A. R. I. B. A., before the Architectural Association and printed in the *Architect*.

well as mental strain, and since practice means the continuance of study and, added to this, responsibility, the profession is certainly not one to be adopted by the physically feeble. But women are not all physically feeble any more than men are all physically strong. You have heard of architects — men — breaking down through overwork, but you would not for that reason say that all men are unfitted to practise the profession. I have never heard of a woman architect breaking down, but neither do I assert that all women are fitted to practise architecture.

Those who base their objections to women architects on the fact that they are an innovation, and therefore to be suppressed, will fling their prejudices and fears to the winds when what is now an innovation comes to be a recognized institution. Already in America one town has a lady for a consulting architect, and we are given to understand that her designs for schools, prisons and railway-stations compare favorably with other similar works in the country.

But there are some opponents who are more specific in their objections, and it is with these we must now deal. Their objections really arise from an imperfect knowledge of what an architect is. There is a general idea that architects "make plans" and climb ladders, but beyond these two accomplishments nothing certain seems to be known. The former occupation is acknowledged to be quite a legitimate one for a woman, provided she have the necessary gifts, but the latter cannot be countenanced for a moment, even though she may be sufficiently courageous to attempt it, and can be trusted not to lose her head on the scaffolding. As far as I can gather, it is not the climbing that is objected to, but the fact that she may be seen climbing a ladder. Therein lies the difficulty. No less an architect than Wren shows us a way round, if not over it. The famous Duchess of Marlborough informs us Wren "was content to be dragged up in a basket, three or four times a week, to the top of St. Paul's, and at great hazard, for £200 a year." No one could object to a woman being hoisted up in a basket any more than they could object to her making use of the more conventional elevator. Climbing a ladder is condemned as unwomanly, but so was riding a bicycle or being seen on the top of an omnibus not so very long ago, and yet all are now seemingly reconciled to these unwomanly practices. Besides, the ladder question could only be raised by persons who are in ignorance of the portion of a lifetime that an architect spends upon a ladder, and as this is so infinitesimal it is unworthy of consideration.

But besides the objector to innovation and the objector to ladder-climbing, there is the man who has dealt personally with achitects as their client, and who knows very definitely what an architect is and what he expects from him. He must be a thoroughly artistic, scientific and practical man. He must be able to design at all possible speed a convenient, durable and beautiful building of any one of the three groups into which buildings may be roughly classified — Domestic, Ecclesiastical and Civil. He must have an intimate and familiar knowledge of every material and every trade employed in the realizing of the said building, in order that none but the best of its kind and the best of technical skill may be employed. He must be a master of scientific construction, in order to prevent waste of time, material and money. He must keep all accounts relating to the work, bear in mind the interests of client and contractor and manage everything without allowing any friction to come about between the parties concerned. This list is not complete; I have mentioned but a few of the functions required by an employer of his architect. For the sake of argument we will suppose that they appear to offer just so many obstacles to a woman following the profession.

I use the word "profession" because it covers more requirements than art, craft, or faculty, and though it has been weighed and found wanting, it appears to be the word in most general use when connected with the practice of architecture.

To succeed in architecture one must be, as I have said, artistic, scientific and practical in business matters; that is to say, success is largely a matter of natural gifts, education and experience. Now, who will assert that the necessary gifts are not and cannot be possessed by woman; that she does not receive the requisite general education, and that experience may not be acquired by her as well as by man?

Let us look first at the æsthetic side of the question. Architecture has been defined as good construction inspired by an artistic motive or by the instinct of the beautiful. Now this instinct of the beautiful, or, as the French put it better, "ce sentiment du beau," is, as a rule, more strongly developed in the woman. Nearly every woman is more or less impressionable, that is, she is an artist by temperament. Her taste will lead her instinctively and intuitively to a result which a man will reach by a series of criticisms and reasonings. He sees the truth, she feels it. The beautiful is attained by both; what matter if the paths they follow are different?

In most cases (outside the profession, be it understood) who is it who cares to be surrounded by beautiful objects and attempts as far as is possible to make the home a thing of beauty? It is certainly not the average man, who, so long as he is comfortable, cares little for the appearance of his surroundings. It follows, then, that it must be the woman who will cheerfully sacrifice even comfort to her conception of beauty, if any choice have to be made between the two.

Some people go so far as to say that a woman must necessarily know how to plan a house better than a man, because her household duties suggest to her the wants and requirements that must be met. We do not agree with this view. The best housekeeper in the world may have most definite ideas as to what she requires, but she will not produce a plan, that is, the suitable disposition of spaces, till she has learned what rules and precepts must be obeyed in planning a house. And these rules, being all based upon common-sense and obvious reasoning, are as patent to men as they are to women.

We must not, however, lose sight of the fact that the influence of woman in domestic architecture has been felt ever since the progress of social relations made her the equal instead of the slave of man. Women's position in a country is the surest sign of the social progress in that country, and it was in the sixteenth century, when women began to be respected "as a whole," and not in individual instances, that domestic architecture regained its prominence. It was when a woman ruled this country, and by her personality influenced many, that castles, cathedrals and colleges — buildings designed by men for men — ceased to be the most important architectural objects erected. Elizabeth's reign is remarkable for the number of radical changes which took place, and in no direction was the change so marked as in architecture.

At the time when, under James's rule, the Scotch were dwelling in fortresses about as comfortable as a Norman keep, the English, under Elizabeth, were vieing with each other as to who should build the most roomy, most convenient and most beautiful houses. It is noteworthy that the great Queen spent not a penny herself in the interest of building, but she gave her noblemen much moral support, encouraging them to spend their thousands in erecting palaces worthy of receiving her as a guest. One of the most indefatigable builders of that time whose name has come down to us was a woman, Elizabeth of Hardwicke. Of the "three most elegant seats that were ever raised by one hand," so says her biographer, only Hardwicke Hall remains, and, judging from its monotonous symmetry and extravagant window-space, we have, it seems, little cause to regret old Chatsworth and Oldcotes. Besides her three country-seats, this lady left "stately almshouses for twelve poor people" in Derby, and personally superintended the construction of "a splendid mural monument" to her own memory in All Saints Church, Derby. Her biographer, alluding to her passion for building, describes her as "a woman of a masculine understanding and conduct; proud, furious, selfish and unfeeling." Apparently we are to gather that these unattractive qualities, pride, violence and egoism, go hand-in-hand with a masculine understanding. If, as Hardwicke shows, she lacked artistic feeling, she was, on the other hand, a thoroughly practical woman. Of the four husbands she outlived, three were wealthy men who were able to supply her with the means of indulging in her favorite pursuit.

In France, where women stand out more prominently than in England, and during the early Renaissance, when they were most conspicuous even as politicians, warriors and poets, we find them occupied with building at an earlier date than at home. Marie de Pierre-Vive, Dame du Perron, one of the ladies of the household of Catherine de' Medici, was officially associated with Philibert de l'Orme during the erection of the Tuileries. In 1566 her name stands among the list of "MM. les Surintendants des Bastiments du Roy," and it is interesting to note that where she and De l'Orme signed papers together, Dame du Perron's name comes first. Her royal mistress was another woman of "a masculine understanding," and insisted on her own plans being used for her palace. De l'Orme writes to her, "Lequel Palays je conduis de votre Grace suivant les dispositions, mesures et commandement qu'il vous a plait m'en faire."

But however artistic a woman may be, her natural gifts alone will not suffice any more than will those of a man, without study and direction. Art has its restrictions and its limitations, which must be recognized and appreciated, if truth and nature are to be our guides; and architecture is particularly restricted and limited in theory and in practice. In theory it is bound by those rules of art inspired by taste based on traditions, and by those rules of science which can be demonstrated by invariable and absolute formulas. And in practice it is limited by structural conditions, which, if neglected, result in the collapse of the building; it is limited by the physical properties of material, by the climate, by the habits and necessities of the moment.

Study of æsthetic rules produces fine designs, and study of scientific laws produces fine construction. Construction demands a knowledge of the principles of mathematics, besides a knowledge of the properties of building-materials. Now, mathematics involve logic, or the science of reasoning correctly, and hitherto logic has been held to be the peculiar inheritance of man as opposed to woman. It may be freely granted that among uneducated women possibly a larger proportion are more illogical in their every-day conclusions than among an equal number of uneducated men; but it by no means follows from this that the brain of the average woman of education is less capable of mastering the science of logic than that of the average man of education. Now, we are only discussing cultivated women, and all reference to the uncultivated and illogical class is beside the question. That logic can be mastered is proved by the successful results achieved by women at the universities, where they show peculiar aptitude for the science of mathematics, the numbers who devote themselves to this study being great, out of all proportion to those who select other schools or triposes. Again, at the Ecole des Beaux-Arts, where the architectural course includes, besides an immense variety of other subjects, a very high standard of mathematical ability, a woman, an American, has lately had the honor of carrying off the Premier Prix over the heads of her brother-students.

But pure mathematics are of little use without familiarity with the properties of building-materials, and this familiarity, it is argued, can only be gained by a technical knowledge of the trades employed in building. In the Middle Ages the architect was only distinguished from the workman by conspicuous natural gifts and greater skill in

technique; he who was most familiar with his materials produced the finest designs. The workshop was then the training-ground for the embryo architect, and doubtless would have proved a rough school for a woman. But now, however much the fact may be deplored, most of the architect's work is produced in an office, and not in a workshop, and is due more to his intellectual activity than to his manual skill in any trade. If, then, good design depends upon the proper use of material, and this use may only be learned through handling it, how comes it that fine designs are produced by men who are in no way fitted to work with such material, and that, on the other hand, most of the builders who dispense with the services of an architect, and many of whom are skilled in one or more trades, produce crude results which, though they strive after, fail to realize, architectural effect? The answer is simple. It is largely a matter of education and preparation which enables the sharpened intelligence to grasp more readily the principles of technical skill. This general education is indispensable to architectural study, and since there is but slight difference nowadays in the course of education pursued by men and women, I cannot see that the absence of workshop training should nowadays hamper a woman more than it does a man. Do not mistake my meaning. Education cannot create the gift of design, for designers, like poets, are born, not made; but it fosters and encourages this gift and calls out the highest faculties when they do exist in the student. No amount of training will make the deaf and dumb to sing; but, for all that, training is invaluable, not to say essential, to a singer who means to do his voice justice. If I may be allowed a misquotation: —

> Books, gowns, degrees will leave a fool a fool,
> But designs are best when the designer's been to school.

Granted, then, that woman is fully competent as far as the æsthetic and scientific sides of the profession are concerned, there remains the economic side to be considered. This covers all the business transactions that take place between the architect, client and contractor, and involves the exercising of a large amount of tact in order to make matters run smoothly. Without tact a business man will not go far, and this indispensable quality seems universally acknowledged to be dealt out more generously to woman than to man. In France every woman is born a business-man, and her taste is never questioned, whereas in England it is the exception to find a man who combines artistic talents with business qualities.

The stumbling-block in the business relations seems to be that the architect is responsible for the quality of the work done, and so has to oversee and direct the workmen. This, for some reason, is supposed to be beyond the powers of a woman; I am told, it is objected, she cannot use the necessary amount of strong language to keep the workmen up to the mark. But surely there are other ways of enforcing your will than through the medium of unseemly language. There is not one man in twenty who has realized that gentleness may be a force. A man will boast of his want of self-control; he flatters himself that abusive language shows him to be a man of strong character, a master; he would count himself less manly were he less violent, and yet you must confess that some of the gentlest men you know happen to be those who always get their own way and compel people to carry out their wishes whether they will or no. St. Paul's Cathedral, one of the finest examples of Renaissance work we have in England, is a living example of what workmen can produce without the stimulus of abuse. Wren held the "ungodly custom of swearing" in such abhorrence that he posted up an order to the effect that, upon sufficient proof, the clerk-of-works should dismiss any laborer guilty of this crime, and further that "if any master working by task shall not upon admonition reform this profanation among his apprentices, servants and laborers, it shall be construed his fault, and he shall be liable to be censured by the Commissioners." Besides, swearing at one's subordinates is really not as fashionable as it used to be. In the army and the navy, where formerly the slightest order was accompanied by a volley of oaths, the change is strongly marked, and the officer who now so far forgets himself as to swear at his men lays himself open to a severe reprimand from those who are of superior rank to that which he holds.

I think I have touched upon most of the points which might be brought forward as objections to women practising architecture, and I trust we shall all be agreed that the obstacles are more imaginary than real. But there is one other point I ought to refer to before closing, and that is the "new style" some people are clamoring for. Since women began to study architecture it has been suggested that they may supply this pretended want, but as yet there has been little to warrant the conjecture that the fresh inspiration will come from that quarter. Women make intelligent interpreters and passionate disciples, but, to judge from the testimony of bygone centuries, their power stops short at creation. It may be wrong to assume that woman is totally wanting in inventiveness, and it may all be a question of upbringing and training. Hitherto men have always led the way, for the race is to the swift and the battle to the strong, and men have been the swift and the strong since women's upbringing taught them only dependence and reliance, and in no way fostered originality. But nowadays women are expected to think and act for themselves, and this self-dependence and self-reliance may prove to be the generating spark which will rouse to activity the originality and creative power which, for all we know to the contrary, may have long lain dormant within them.

But in any case this want of creative faculty would not hamper a woman architect. Architecture is a logical art, and no change has taken place in it without a very obvious reason, and when no reason can be adduced for original and capricious designs, such productions are grotesque and not architectural. The truest architects are not distinguished for brilliancy of invention so much as for careful attention bestowed on the smallest details of their work, and women, "as a whole," possess the faculty of worrying out details so small that they often are apt to escape the attention of the more comprehensive mind of men.

If I do not stop now you may go away with the impression that I consider women more fitted to practise architecture than men, and nothing could be further from my thoughts. May I, in concluding, repeat what I said at the beginning of my paper, that it is not a question of men *versus* women, but that it is entirely a case of the capacity of the individual?

A FOUNDATION ON QUICKSAND.[1]

MERIDEN lies in a valley between high hills. In the valley, which is claimed by some to be the original bed of the Connecticut River, is a soil which consists of a sandy loam, a little gravel and plenty of quicksand. Most of the buildings in this valley rest on the skin which is found at various depths below the surface, and here the Meriden Gas-light Company bought a 300′ x 500′ meadow-lot adjoining its works on which to erect a new holder. Careful borings were made over a section 120 feet wide by 250 feet long to determine the thickness of the gravel, if any, and its distance below the surface. To the west of this section, and 25 feet distant, runs a shallow brook, 20 to 30 feet wide — shallow except in freshet time. About seventy-five tests were taken, and the result laid out and plotted into curves, so that the most desirable place for the site might be located. The top material was a sandy loam, evidently a silt deposited from the overflow of the brook when in past years it was not so confined; the next, a good gravel, but very thin; below that, a quicksand of unknown depth. At a few points the gravel was found as near as 2 feet from the surface and 2 feet thick, while at the others it was 8.5 deep and only .4 thick, shading off to nothing. The average depth, however, taken from the boring-stations, was 5.5 feet deep and 1.2 feet thick. A boring of 50 feet taken in the centre of the site showed 42 feet of quicksand and still more below.

On such materials it was decided to construct the foundation and erect a steel tank-holder, to be 115 feet in diameter and 103 feet high, holding 700,000 feet of gas in three lifts; the weight of the holder to be 475 tons and the weight of the water to be 8,625 tons, or a total of 9,100 tons.

As the work of excavating progressed and the gravel was exposed, there was found a clearly defined depression diagonally across the pit, as if at some time the brook had flowed that way; for logs and trunks of trees were found together with a quantity of brush. Through this depression the gravel was very thin, and in three places the quicksand was entirely exposed — the first, a space 10′ x 15′; the second, a space 4′ x 12′; the third, a space 3′ x 15′.

Hardly had the whole of the loam been removed when a rain came, followed by a heavy freshet, overflowing the meadow and deluging the pit. When the water had subsided it was pumped out in 8 hours with a 4-inch centrifugal pump and a 7½-horsepower motor, though the water was 10 feet deep in some places. The freshet convinced the Company more than ever that in erecting a holder it would be advisable to make the top of the foundation above high-water mark, which in this case would mean a fill in some spots of 12 feet, with an average of 8 feet, and the steel tank would be 2.5 feet above the level of the meadow.

At this point a difficult problem was confronted. Meriden topographically is on high hills and in a sandy valley; good gravel is a very scarce article. Four miles away, on the line of the railroad, is a large, poor gravel bank, and two miles in another direction is a small, good bank; but with all the teams that could be procured it was not possible to haul the material as fast as it was needed; and it was expensive — $1.00 per yard delivered. It was evident that other and good material must be obtained in large quantities. On the line of the railroad three miles away is a large trap-rock quarry. Refuse in the shape of iron-stone, soft-rock and some dirt is accumulated in large quantities. It was believed this stone would mix well with the material which was on hand and could be purchased after it had been passed through the crusher to a 1½-inch size, at 60 cents per yard delivered and in quantities up to 150 yards per day. About 50 yards of gravel and 50 yards of clean, sharp sand could also be procured each day, and as much ashes from the works as there were teams to put on it.

The question of piling was considered, and by some might seem the only wise plan under the circumstances, but after consulting the leading local builder, who had worked on this quicksand for thirty years and had erected some very heavy factory-buildings on it, it was thought best to put in a combination filling of the above-named materials.

The quicksand is found hard packed and not easily dug, unless water is allowed to mix freely with it. Although the excavation was in places much below the level of the brook, little water was encountered, and quite as much came from the land as from the brook side. By keeping the bare spots well drained the men could work on the quicksand with a degree of ease without sinking in very deep; the less it was disturbed, however, the better off they were. Over

[1] From a paper by Mr. C. A. Learned, read before the New England Association of Gas Engineers.

these bare spots it was decided to lay plank close together lengthways of the holes, and upon these 8 by 10-inch timbers, 8 inches apart, crossways of the holes. The filling between the timbers was of pieces of bricks and old retorts broken up fine, that being the best material at hand just then. One of the bare spots being narrow and long, the surface was covered with large flat stones, the smaller spaces being filled-in with fire-bricks and coarse ashes.

While working at this low level a pump was run night and day; also from these quicksand spots a 4-inch-tile drain was laid to a central point to facilitate drainage and keep the mass from becoming spongy while the tamping was going on and each course of filling was laid.

Until the whole surface approached a level no roller could be used, but everything put in was thoroughly rammed and sprinkled. The layers were about 3 inches thick over the whole surface. When the valleys were evened up a two-horse 4,000-lb. roller was put on, and as the thickness became greater this roller was increased in weight to 6,500 lbs., requiring four horses. When the level of filling had been raised above the natural water-level the pumping was dispensed with over night, allowing the foundation to be saturated, but it was pumped out again in the morning.

Near the centre of the foundation a loose brick well was built up, into which the water ran as the foundation was successively wetted, and from which it was pumped to the brook. There were some high knolls of gravel not over 3 feet under the surface. It was thought at first that the 5-foot concrete side-wall foundation might rest on these, but further consideration convinced the Company that this was not advisable, as part of the foundation would rest on natural gravel, while most of it would be on filled ground, so the whole level was raised 1 foot to allow of the same kind of cushion underneath the whole structure before the 5-foot circle was started.

The layers spread each day over a diameter of 125 feet were about as follows: — 125 yards of quarry refuse, 40 yards of good gravel, 50 yards of works' ashes. Towards the end of the work the ashes were exhausted. Near by was a bank of 500 yards of sand, and from this was taken what was needed to make the top-dressing under the concrete, spreading on the stone, washing it in and carefully rolling. Toward the end the roller worked night and day.

Near the edge where the wall of concrete was laid, there was a space that could not be rolled, but had to be filled and tamped to a depth of 4 feet. In order to make sure that this portion was as solid as the centre, a round tapering bar 5 feet long was driven into the main foundation several times. Seventy blows on the average were required to drive it 4.5 feet, and the outside ring was tamped until it equalled the above test.

The amount of material removed approximated 2,900 yards. The work of excavating and filling ready to begin concreting took twenty-two days, and six days more were required to fill-in around the great circle after the concrete wall was 4 feet high. This, however, did not delay the concreters in their work. The filling was as per the following amounts: Quarry stone or refuse, 1,780 yards; gravel, 680 yards; sand, 310 yards; ashes, 1,100 yards; total, 3,870 yards.

On this foundation was laid 630 yards of Portland-cement concrete, in the following proportions: 1 of cement, 2½ of sand and 5 of stone. The size of stone was 1¼ inch and smaller. A great circle of concrete 4 feet wide and 1 foot thick was laid 5 feet below the finished top. On this circle was laid a ring 3 feet wide at the bottom, tapering to 2 feet 9 inches wide at the top, and 3 feet high; resting on the ring was laid, over the whole diameter of 118 feet, a layer 1 foot thick, trued to perfect level and plastered smooth. This work was accomplished in eighteen days, and in a most satisfactory manner, a local engineer taking the job at $4.90 per cubic yard laid. As soon as the foundation was ready the iron-men were on the ground, and the holder was erected complete in a week less than the specified time of four months.

In order to prevent the action of the brook eating away the bank near the holder, a stone wall 7 feet high was built to the level of the holder foundation and 400 feet long, protecting also a new purifier building near the brook. City water was used to fill the tank, as the brook water contained acids. It took three and a half days to fill the tank, which holds a little over 2,000,000 gallons. Before the water was put in careful levels were taken on eight points of the foundations. After filling levels were again taken, and there was not the slightest settlement.

SOCIETIES

THE ARCHITECTURAL LEAGUE OF AMERICA.

THE Fourth Annual Convention of the Architectural League of America will be held at Toronto, Canada, on Thursday, Friday and Saturday May 29, 30 and 31, 1902.

The Architectural Eighteen Club of Toronto, hosts for the occasion, and the various Committees are endeavoring to secure good speakers and to make the occasion profitable and entertaining.

The topics for discussion will follow in the main those of last year, special attention being given to Municipal Improvement, Architectural Education and the various departments of Architectural Club-work.

HUGH M. G. GARDEN, *Secretary.*

DANGER FROM WOODEN STAGING IN WESTMINSTER ABBEY.

25 CATHERINE ST., NEWPORT, R. I., April 13, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — It is with the greatest distress and the gravest apprehension that I see that loads of timber and lumber are being taken to Westminster Abbey and carried into the building to construct the staging for the coronation. Should fire get into this lumber (a likely event), then Westminster Abbey, one of the most exquisite of Gothic creations, would be lost to the world.

It is easy to see how staging can be made of wrought-iron slats, pinned together through holes punched in them beforehand, with nuts and bolt-heads screwed on to the ends of the pins. Such staging can be made to conform to any arrangement for the seating desired. The floors under the seats can be of boiler-plate, noise from which can be deadened by thick carpets and layers of linoleum. The seats can be the usual cast-iron once common in our theatres, with stuffings of asbestos.

Will not some American firm offer to contract for such staging and send for plans of the arrangement of seats desired? There was a firm (I have forgotten the name) who had an office in the Charities Building on Fourth Avenue near Twenty-second Street, New York. They did work for me on the Colt Memorial Building in Hartford in 1895, and could do such work as this well.

Will not the *American Architect* give a wide publicity to this word of warning? Respectfully yours,

EDWARD T. POTTER, *Architect.*

THE "EXUBERANCE" OF MESSRS. HORGAN & SLATTERY.

NEW YORK, N. Y., April 15, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — We have read with much interest and wish to thank you for your clear exposition of the facts in connection with our employment as architects for the preparation of plans and specifications for the 69th Regiment Armory Building.

We fear that, not having the facts before you, you have unwittingly done us an injustice in your remarks as to the exuberance of the design published in your last issue of the building No. 918 West End Ave., New York. We beg to state that the ornamental lamps, shields, stained-glass, etc., shown on the elevation were not designed by us, but were erected by a Brazilian who became the owner of the building nearly two years subsequent to the completion of the building by us.

We also send photograph of the building, taken when we completed same, and we think you will agree with us it is hardly exuberant in its details. Very truly yours,

HORGAN & SLATTERY.

[THE photograph referred to shows that the exuberant ironmongery was added after the house was completed. — EDS. AMERICAN ARCHITECT.]

NOTES AND CLIPPINGS

ELECTRICITY IN EGYPTIAN TEMPLES. — Electricity is to be used in lighting the ancient Egyptian temples of Luxor and Karnak.—*Exchange.*

THE ROLAND PILLARS. — In many parts of Germany one finds in market-towns a rude effigy in stone called Rolandsäule, which is supposed to represent the famous Paladin of Charles the Great. There was one in Berlin which suffered ignominious treatment owing to the changes in taste and is now deeply regretted by the local antiquarians, while a number of the minor towns of Prussia find their old market-statue the most attractive thing to show visitors. Most famous of all is the Rolandsäule at Bremen. The enormous popularity of the versified tales in which Roland figured from the tenth century onward throughout the West of Europe may account for these statues; or, if they were not originally meant as monuments to Roland, may explain the attribution of them to the Paladin. In France a suggestion has been made to erect a memorial to Roland, who was an historical personage named Hruodland, Prefect of Brittany under Charles the Great. He was overwhelmed with the rearguard in 778 by the Basques while retreating from Spain. Hruodland, or Orlando, as the Italians called him, is certainly one of the most famous Frenchmen known to history, about whom a more poetic nimbus has gathered than about Charles the Great or Napoleon. So a fund has been launched in Paris which when large enough is to provide that fair city with a monument to the hero of a thousand songs, epics, plays, a Teutonic general whose character has been invested with traits borrowed from Celtic culture-heroes and ancient Romans of history and romance. The German colossal statues named for Roland in all probability were erected by citizens of certain towns to attract the ignorant, half-pagan rustics, thus affording them a substitute for their old idols, and they were placed at the town-hall or in the market so that bargains might be sealed before them. The Paris Roland will form only one of a thousand statues which attract Christian as well as pagan foreigners to the French capital. — *N. Y. Times.*

IS FORTY-FIVE THE AGE-LIMIT FOR LABOR? — Is it true that employers of labor are discharging employés who have reached the age of forty-five, whether they are capable or not? Do they decline to take on new men who have reached this age? At a meeting of the Chicago Federation of Labor, held a few weeks ago, statements were made that these were existing facts. Members present testified that they had been obliged to dye their hair when it turned gray, to cut off their beards which were becoming white, and leave their spectacles at home, in order to look younger than forty-five, or they could not get a job. The discussion was serious, and some excitement prevailed, so much so that one member sarcastically observed that employers ought to make a law providing for the shooting of all laborers who had reached the age of forty-five. No doubt there is some truth in this. Certain employers may try to get rid of old men and look for young ones, but it is impossible to change the law of nature that a man who is worth his pay, whatever that is, can get work in this country, no matter what his age. If he is twenty-five and incompetent, he cannot keep a job, nor can he at forty-five. If he is active and intelligent, he will in time get what men of the same activity and intelligence command, no matter what his age. The truth probably is that so many workmen of forty-five have lived a hard life and have lost their abilities that they are not worth the money; and employers, seeing the rule, cannot be persuaded to make exceptions. But, after all, the Labor Federation should bear in mind that any resolutions on their part that tend to prescribe whom employers shall employ are, and always will be, unsound, and can only redound to their own injury. — *Harper's Weekly.*

THE RETIRING-AGE FOR WORKMEN. — Every little while a discussion arises as to the time of life when a man ought to retire from active participation in affairs. The public is asked to consider whether there is not a certain limit of years when a man no longer ought to preach, when a rich man ought to begin to give away his money, when a farmer ought to hand over his fields and granaries to his sons and daughters, when an editor ought to stop writing anything but reminiscences which he is pretty sure nobody will read. Out in Minnesota the other day a logging-party, returning from its winter camp, was found to consist of one contractor, aged seventy-eight; another contractor, aged sixty-five; one helper, aged seventy-nine; one horse, aged twenty-three, and another horse, aged twenty-one. They built their own camp, cut their own roads, and piled upon the frozen lake 100,000 feet of pine timber. Further than these bare details the chronicle is silent, but there is enough to show that in the logging-camps of Minnesota the question of the age of retirement is still under debate, or has been indefinitely postponed. — *Exchange.*

GREEK COLUMNS. — So far from employing pedestals to columns, which some have considered as forming as essential a part of an order as the entablature, the Greeks placed their columns immediately on the floor or uppermost step, the whole temple being generally raised on a low platform, to which the ascent was usually by three deep steps or *gradini*, serving as a base to the edifice; the depth of the steps was not accommodated to the human stature, but regulated so as to accord with the dimensions of the column. It is, therefore, conjectured that either a sloping platform of wood or lesser steps of the same material were employed as the real ascent to the temple. The Greeks invariably placed their columns singly, never in pairs, as has frequently been done by modern architects, and which, if not utterly indefensible, ought never to be resorted to unless required by positive necessity: for instance, where wider intercolumns than the scale of the order will properly admit are required, in which case, by affording additional support to the entablature, coupled columns not only excuse the width of the intervals, but take away the air of poverty that would result from single columns placed at the same distance from each other. Coupled columns are most of all offensive when forming a prostyle colonnade, especially if it be one with a pediment, since that disposition approximates so closely to that of the front of an ancient temple as to render any incongruity the more striking. — *The Architect.*

SEQUEL OF THE CHIGI BOTTICELLI SALE. — The suit of the Italian Government against Prince Chigi for having sold his famous Botticelli to Mrs. Gardner, of Boston, has resulted in a manner to make other owners of valuable art-works more careful. The Prince is ordered to buy the picture back or, failing that, to forfeit its value in money to the State. That the Government means to carry out the law forbidding such sales is also shown by the fine of $28,000 imposed upon Enrico Pardo for having sold to a foreigner the Cellini bust of Altovito, formerly in the Altovito Palace in Rome. — *N. Y. Evening Post.*

CURIOUS EFFECT OF CHEMICALS ON SEA-WATER. — While M. Santos-Dumont was inflating the balloon of his No. 6 air-ship at Monaco, he was commanded by the authorities to cease immediately the process of hydrogen-making, on account of the extraordinary effect that the drainage of refuse acids and chemicals into the bay was having on the water, which had turned a brilliant orange, and which it was feared might have an injurious effect on residents near the sea-front, besides poisoning the fish. Subsequent investigations of the curious phenomenon, however, proved that the refuse sulphates running from the Dumont gas-house into the sea had, on contact with the chloride of sodium, or common salt of the ocean, precipitated enormous quantities of oxide of iron. This pure rust had dyed the waters and the shore a most brilliant orange carmine, but except for this no harm was done. Beyond acting as a tonic for the fish, the rust was absolutely innocuous, and the work of inflation was forthwith resumed. — *Scientific American.*

THE EXCAVATIONS AT CARTHAGE. — The Académie des Inscriptions et Belles-Lettres, says the Paris correspondent of *The Times*, has voted 30,000 francs to Father Delattre in order to enable him to continue his excavations on the site of Carthage.

THE USE OF MAGNETITE IN CONCRETE. — A writer in *Nature* points out the advantage that would be gained by the use of magnetic-iron ore as a material for concrete blocks. He points out that if magnetite is used instead of ordinary rock in the shape of fragments, and magnetic sand or ilmenite sand instead of common sea-sand, concrete blocks can be obtained which have all the strength of the ordinary concrete blocks, and which weigh, when immersed in water, exactly twice as much as the ordinary blocks. Such an increase in weight makes the magnetic blocks far superior as regards resistance to the waves. Work constructed with magnetic blocks will stand when other work will be destroyed.

BROCK'S "LORD LEIGHTON" CAST IN BELGIUM. — The recumbent bronze figure of the late Lord Leighton for St. Paul's Cathedral, London, modelled by the sculptor Brock, was cast in Belgium, and the marble pedestal was also fashioned in pieces on the Continent and sent across the Channel to be erected. According to the statement of a member of the Leighton Fund Committee, made to a London paper, "The work could not be done in England; that was why it has been done abroad. Mr. Brock would not intrust a work of this importance to English founders. Any one who knows anything about such things is aware that this is why such work goes to Belgium." The explanation is received with no little dismay in London. Certainly, it would not be true of the United States. — *N. Y. Times.*

CANONS' STALLS FOR WESTMINSTER CATHEDRAL. — The luck of Cardinal Vaughan in the building of his cathedral seems to extend even to details. His fifty-four canons' stalls, which formerly stood in the Monastery Church of St. Urban, near Lucerne, will be the finest of their kind in London. The late Lord Kinnoull bought them in 1866 and bore them to Dapplin in forty trucks. One tires of toys, especially of toys of that size, and the present Lord Kinnoull, willing to clear out his stalls, fixed as their price the modest sum of £4,000. Cardinal Vaughan saw, and was delighted with what he saw, but did not think he could seat his canons so expensively. Then the usual benefactor stepped forward just in time, put down his check, and presented the carved furniture to the hesitating but not lost Cardinal. — *London Chronicle.*

THE LIGHTNING-ROD QUESTION. — The vexed lightning-rod question is now under consideration of the Special Lightning Research Committee which was organized last year by the Royal Institute of British Architects' and the Surveyors' Institution. More than 200 competent observers have been appointed in the United Kingdom, the Colonies, India, and elsewhere. The British War Office, the Home Office, the Post-office, the Trinity House Corporation, and the United States Department of Agriculture have agreed to furnish the Committee with particulars of damage resulting from lightning-stroke to buildings under their control. The heavy thunder-storms of last year afforded many opportunities of investigating and recording, upon prescribed lines, the damage caused by lightning. The net result, so far, is a series of seventy or more trustworthy records, which furnish promising material for the Committee to work upon, with the view of formulating conclusions. The Committee have arranged for getting photographs immediately after the occurrence of a disaster in cases of importance. Out of sixty cases tabulated up to the end of December, no fewer than twelve relate to buildings fitted with some form of lightning-conductor. As regards the system recommended by the Lightning-rod Conference of 1882, the facts at hand are not sufficient to determine the extent of its efficacy. The recently issued report, however, of the British Inspectors of Explosives goes to show that it has been found wanting, and that there is ample justification for the present inquiry. The head of the Committee is Mr. John Slater, the eminent architect, and among his associates are Dr. Oliver Lodge, W. P. Goulding, Major-General Festing, and other well-known scientists. — *N. Y. Evening Post.*

NOTES AND CLIPPINGS. 32

INDICATIONS point, perhaps more distinctly than ever, to an approaching movement in real estate, which, it may be hoped, will be for the advantage of building-interests. For some years, construction has been, to a great extent, confined to syndicate operations, which have been devoted almost exclusively to office-buildings and apartment-houses. Now, there are evidences that the production of new offices has run rather ahead of the demand; and, except in New York, which seems to have an unlimited market for tenements of all classes, the cost of first-class apartments, and the expense of maintaining them, is so great, and their tenancy so uncertain, that syndicate managers, who look for a sure, rather than a large, income on the investment which they control, look upon them with diminishing favor. Meanwhile, however, the country has for several years been extremely prosperous, so that there is a large amount of money seeking investment; immigration has increased enormously, bringing in, under our present laws, a new population of industrious and thrifty citizens; and these new citizens will soon need houses, and those who sell goods to them will need new stores for their business. All this will bring about a renewed demand for varieties of property which have for several years been neglected, and for new construction in many forms. In fact, rents of dwelling-houses and stores have already advanced slightly, and, even at present rates, they pay much better interest on the investment than the railroad stocks which have doubled in price within the last two or three years. Most experienced bankers think that the prices of the latter have reached their highest point, and the appearance of the seventeen-year grasshopper, or a season of hot winds, might reduce them very materially, while prices of real estate, on the whole, have remained stationary for at least twenty years, and a readjustment of the value of such property to the present population of the country would involve a very large advance. That such readjustment must come sooner or later is certain, and the prices of available land which seemed reasonable when the country had less than forty million inhabitants will appear absurdly low with a population of seventy-five millions. It is true that a great deal of land has been "developed" within the last two or three decades, and that the competition of the newly-developed property has kept down the prices of other land; but development now concerns itself mainly with suburban lands, and the improvement of these will, in the end, add to the value of city property, the area of which is necessarily limited.

A TRUST is said to have been formed to control the output of whitewood, or poplar, as it is called where it is grown. This timber, the wood of the tulip-tree, or liriodendron, is produced only in a limited district, in Tennessee, West Virginia and the neighboring States, and it seems to have been an easy matter to combine the saw-mills of the region under a single management. As usual with trusts, the public is assured that the monopoly will not result in raising the prices of whitewood lumber, but is intended only to secure profitable and economical use of the waste matters from the mills. Whether these reassuring statements will be confirmed by experience remains to be seen, but the poor owners and tenants of houses, who have seen the prices of framing and flooring lumber, protected by a heavy duty against the competition of Canadian forests, nearly doubled within a few years, and those of hardware, glass and metalwork, controlled by trusts under the protection of the tariff, more than doubled, are not likely to put much faith in them.

IF the poor workingmen, and people dependent upon salaries, had their incomes doubled, to correspond with the advance in trust prices, they might not complain, but this is far from being the case, and it does not require a profound intellect to see that every dollar of the annual dividends of one hundred and forty per cent on the real capital of trust corporations, and of the enormous incomes of the financiers who manage them, comes out of the pockets of the great mass of modest and uncomplaining people, who can do nothing but submit to what they cannot prevent. The latest trust, that controlling food products, has excited more indignation than any other, but the protective duties on which it depends for shutting out the competition of Canadian eggs, butter and other provisions are low in comparison with those on other goods, and the tenant of a New York flat has probably paid more indirectly every year for a long period, in his rent, as his contribution to the tinplate trust, the glass trust, the hardware trust, the iron trust and a dozen other trusts, than he will this year directly to the beef trust in the increased prices of the food which his family consumes.

THE delights of the tariff continue to occupy a considerable portion of the attention of the public. By the generosity of friends of the United States in France, a statue of Admiral Rochambeau has been made, for presentation to the Government, as an ornament of the city of Washington. Considering the important share which our French allies had in bringing about the success of our Revolution, and the pleasure which all Frenchmen take in recalling their participation in the struggle which gave birth to the great Republic, the gift of the Rochambeau statue was a particularly graceful and significant international compliment, and it was with mingled feelings, in which, we may suppose, admiration for American courtesy did not form a very large ingredient, that the officials of the French Embassy learned that a duty of thirty-five hundred dollars would be levied upon the statue on its arrival in New York. On application to the Treasury authorities, the French officials were kindly informed that some one would have to pay the duty on the arrival of the statue, and that, afterwards, by petitioning Congress to pass an act of reimbursement, he might possibly, some time, get his money back. As volunteers for the duty of paying thirty-five hundred dollars to the intended beneficiary of the gift, to induce him to accept it, do not seem to have offered themselves, the prospect is that the Rochambeau statue, on reaching its destination, will either be seized and forfeited, or will be consigned to the appraisers' stores, there to remain until its turn comes to be sold at auction as old junk.

A STILL more chilling reception has been given to the La Fayette relics, collected with great trouble and expense by the American Ambassador to France, for presentation to the Congressional Library. The money required for the purpose, amounting to a very large sum, was contributed jointly by Mr. J. Pierpont Morgan and Mr. Levi P. Morton, and the collection would have been, probably, the most valuable historical treasure in the country. In fact, the custom-house officials in New York were so impressed with its value that they immediately levied a duty of forty thousand dollars on it. Whether Messrs. Morgan and Morton paid the duty, as the penalty for trying to do a good deed to their fellow-citizens, or whether the La Fayette relics were confiscated, or sent to the appraisers' stores as old junk, we are not informed, but it is, at least, safe to remark that it is not under such conditions as these that a country becomes rapidly enriched with historical and artistic treasures.

Entered at the Post-Office at Boston as second-class matter

THE award of the jury in the competition for the Grant statue in Washington does not seem to give universal satisfaction. The first place was awarded to the model of Henry Merwin Shrady, of New York, a young and comparatively unknown sculptor, while the second place was given to Mr. Niehaus, one of the most distinguished of American artists. Whether the jury could not quite make up its mind that it preferred Mr. Shrady's model, or whether it thought that Mr. Niehaus ought really to have another chance, does not appear, but it recommended that a second competition should be held between these two artists. Mr. Niehaus, very honorably, declined to engage in a second competition, so that the work is likely to be awarded to Mr. Shrady, whose friends, while they rejoice at his success, regard as an undeserved and unnecessary discourtesy the suggestion that he should be obliged to compete again for the prize which he had already won in strict compliance with the terms of the programme.

FRANCE has lost a great artist in the sculptor, Jules Dalou, who died recently in Paris, at the age of sixty-four. Dalou was a Parisian by birth, and was educated at the School of Fine-Arts. Like so many other young artists of the time, he interested himself on the side of the Commune during the sad days of 1870, and held office for a time under it. In consequence of this, although it does not appear that he was ever charged with any of the crimes which were expiated at Satory, he felt himself obliged, on the recapture of Paris by the Versaillists, to make his escape to England, where he lived for many years. He returned, however, to Paris twenty or twenty-five years ago, and was welcomed as his talents deserved. He was almost immediately employed to carry out the magnificent group in the Place de la République which would alone secure to any sculptor immortal fame, and, for the rest of his life, was actively engaged in important commissions. Although, among the great artists who have made the French sculpture of the last portion of the nineteenth century famous, there are, perhaps, some whose talent is more sympathetic, none have shown more fire and nobility of spirit than Dalou, and the world will long keep him in grateful remembrance.

THE *Deutsche Bauzeitung* gives some interesting plans and half-tone pictures of the new buildings in the Zoölogical Garden at Berlin. The buildings are by architects of the highest reputation, and are carried out with a freedom and wealth of resource which are rarely seen in modern work. In the elephant-house, for example, by Messrs. Ende & Böckmann, the building, rather simple in plan, has its two entrances accentuated by domes, or, rather, lofty roofs of curved outline, which are covered, apparently with enamelled tiles, in such a way as to form patterns, suggesting, more or less closely, winged serpents, dragons and elephants, arranged in panels, with a background suggesting a Turkish rug. The effect of this novel ornamentation, so far as can be judged from the photographs, is solid and architectural, as well as extremely interesting, and we are disposed to say that it furnishes a signal example of the advantage which architectural design can almost always derive, in difficult situations, by turning to nature for suggestions. Another pretty building, the antelope-house, also by Messrs. Ende & Böckmann, is treated with a similar mixture of architectural and natural forms, but less boldly, and with a success less conspicuous. One can hardly avoid comparing these remarkably interesting buildings with the temporary structures of the Paris Exposition. Although the latter were only intended for six months' use, while those in Berlin are permanent, both were purposely designed to express a certain festive gayety. In both, the outlines were broken, to attract attention, and the detail was studied to amuse as well as interest; but, notwithstanding the beautiful relief-work which was used in profusion in Paris, and the masterly way in which the masses were arranged and subordinated, the temporary buildings of the Exposition, with certain exceptions, unquestionably failed to interest the general public. Architects in Paris, recognizing this fact, account for it by saying that the public did not appreciate the distinction which the profession would naturally make between a temporary and a permanent structure; and, comparing the buildings in plaster and staff with those of stone, found extravagance and frivolity where an architect would see only a gayety suited to the occasion; but the Berlin buildings, although they arrest the attention more effectively than those in Paris, do not, in spite of their gay colors, give the least impression of frivolity. This great merit seems to us to be due mainly to the use of natural forms, on a large scale, as the basis of the decoration, in place of mere bizarre combinations of architectural elements; and we hope that the lesson will not be lost upon the architects of other places besides Berlin.

CONSIDERING how poor this country is in the zoölogical gardens which form one of the most attractive features of nearly every important city on the Continent, it is interesting to note the figures which the *Deutsche Bauzeitung* gives of the financial features of the establishment at Berlin. Like the magnificent Zoölogical Gardens in London, and, if we are not mistaken, the smaller, but very beautiful and interesting ones at Amsterdam and Frankfort, that at Berlin is a private enterprise, carried out and maintained by an association of amateurs of natural history. This association has two thousand members, who are stockholders in the enterprise, and who, with their families, have free admission to the Garden at all times. Besides the stockholders, there are three thousand subscribing members, who pay a certain sum annually, and also enjoy, with their families, the free use of the Garden. These two classes of members make ample use of their privilege, the average number of admissions on stockholders' and subscribers' tickets alone varying from five to ten thousand a day. Besides these, from three to four thousand people per day pay the full admission-price, of one mark, or twenty-four cents, while some two thousand more come at seven o'clock in the evening, at half-price, to listen to the open-air concerts which are given through the summer. On certain Sunday afternoons, also, known as the "cheap Sundays," the price of admission is reduced to six cents, and on these days there are often one hundred thousand people in the grounds. The financial management of the Association seems to be particularly good, for the shares sell at a large premium, a new issue of stock, made for the purpose of raising money for the recent improvements, having been immediately taken up, at thirty per cent advance over the par value. As a part of the money raised in this way is to be used in constructing buildings suited to winter entertainments, a concert-hall capable of accommodating ten thousand people being one of them, it may be presumed that the additional capital will earn a large interest, by drawing to the Garden in cold or rainy weather at least a portion of the people who have hitherto visited it only on pleasant days in summer.

THE beautiful little city of Innsbrück, the capital of Austrian Tyrol, encircled with lofty mountains, is to be the scene next September of an international Congress of the History of Art. The last Congress of the kind was held in Lübeck two years ago, and, before adjourning, unanimously chose Innsbrück as the next meeting-place. For many reasons, it would have been difficult to make a better choice. Not only does the little Tyrolese city have a September climate which is very near perfection, but it is plentifully provided with excellent hotels, which are filled with tourists earlier in the season, but, in September, are likely to have room enough for the members of the Congress. Moreover, lying, as it does, at the intersection of the great Brenner route between Germany and Italy, and the equally important Arlberg route, which connects France, and Western Europe generally, with Vienna, the Danube provinces and Constantinople, it is, and has been for ages, a sort of meeting-place for Northern and Southern, Eastern and Western art. For the purposes of this Congress, the fact that Verona, Venice, Munich, Vienna, Paris, Dresden and Berlin are all within a few hours' ride will do much to make the membership, as well as the exhibits which it is hoped to collect, peculiarly cosmopolitan. The Congress will open September 9, and continue four days. Persons wishing for further information should write to Prof. Dr. Hans Semper, Innsbrück, Austria. Notices of intention to participate in the Congress will be received until August 1, at the same address.

THE cessation of the exportation of American iron to Europe has been followed by a revival of business, and the raising of prices, in all the European markets. In England, particularly, a great deal of iron is now sold for exportation, much of it coming, it is said, to the United States, notwithstanding the enormous duty. Even coal, although the competition of West Virginia and Canadian coal continues, is rising in price in England, a sign of the general revival of manufacturing in that country.

DOMESTIC ARCHITECTURE IN ENGLAND DURING THE MIDDLE AGES.[1]—VII.

TUDOR PERIOD.

THE style of architecture commonly called Tudor extended through the reigns of the Tudor Kings, Henry VII, Henry VIII, Edward VI, Mary and Elizabeth; from 1485 to 1603.

Under the Tudors there came a change over the spirit of the government of the country; the tendency was to make the King all-powerful for the better maintenance of law and order and the more efficient control of the nobles. War, the headsman's axe, attainder and forfeiture had thinned and broken the old nobility, and every effort was made to extort money from and crush those that remained.

Henry VII erected the celebrated monumental chapel, known by his name, at Westminster, one of the leading landmarks of the period, in which he was ultimately entombed. He fostered the arts, inviting sculptors and other artists to come over from Italy, where the great "revival of letters" was already fully established.[2] Saint Peter's at Rome was at that time under construction by Bramante, who was succeeded by Michael Angelo, Raphael and others, contemporaries of the Tudor Kings. Thus at this time were sown the seeds of that great change of taste and feeling that at a later period led to the decadence of mediæval architecture in England, and the revival of the still more ancient arts of Greece and Rome that, flourishing long antecedent to the Christian era, culminated in the splendors of Rome during the Augustan age.

Henry VIII was a man of intellectual training, a good scholar, skilled in music and fully capable of entering into and appreciating the new learning and culture of the age. He was also in his younger days a thorough master of the national weapon, the bow, and was perfect in all those knightly exercises with sword and lance that men deemed the necessary accomplishments of the gentleman of the period. It was during this reign that Francis I inaugurated the era of regal magnificence in France, the days of the "Field of the Cloth of Gold." It was during this time that such buildings of world-wide reputation were erected as the châteaux of Blois, Chambord and Fontainebleau, the Louvre and many others in France, and Heidelberg, on the Rhine.

Haddon Hall: The Entrance.

Cardinal Wolsey, Archbishop of York and Chancellor of England, was one of the leading men of the time, building Hampton Court, on the Thames, one of the most typical works of the period, Barnboro Hall, near Doncaster, and others.

Henry VIII undertook to reform the, so-called, ecclesiastical abuses of the Church; he terminated the payment of tribute to Rome, which had been regularly subscribed by England since the time of King John in 1213, and he declared himself "Supreme head of the Church of England," denial of which was made "high treason." This act caused many notable persons, like Sir Thomas More, to suffer death under the headsman's axe, with attainder and confiscation of their estates. By his dealings with the Church Henry became, incidentally, the leading agent of the "Reformation," a movement that in its inception was more political than religious, the mass of the people being more opposed to the ecclesiastical *power* than to the doctrines of the Church of Rome. The partisans of the movement quickly became parties in the State, those adhering to the reformed church being recognized as "Protestants," those adhering to the Pope as "Roman Catholics," Romanists or Papists.

In 1536, in conformity with this policy, the smaller monasteries were dissolved by Act of Parliament, and three years later the confiscation and destruction of the larger houses commenced, and many famous shrines and relics were ruthlessly destroyed. Of the vast wealth thus thrown into the King's hands part went to found new bishopries, part to fortify the coast; but much more was distributed in lavish grants of estate to favorite courtiers, and many of the abbey churches and buildings were actually dismantled by their new owners for the sake of the lead on their roofs. Thus the glorious monuments of mediæval architecture in England were despoiled and given over to decay; but even in their ruins they are the pride of the land.

It was in times like these that the estates of the loyal Barons were rapidly extended in area. Those of the Duke of Northumberland may be cited as a typical example, owning, as he does at the present time, over 200,000 acres of land yielding a rent-roll of $900,000 per annum. His estates stretch across the north of England from sea to sea and he can ride 100 miles across without leaving his own demesne.

In King Edward VI's time many old foundations were revived and reëndowed, like the "Blue Coat School," Charter House, St. Bartholomew's Hospital, etc., in London, and grammar-schools were erected all over England, many of which remain to the present time, as at King's Norton, Worcestershire, the lower story of which is brick and stone and the upper portions in half-timber with the characteristic open-timber roof of the period.

With Elizabeth came calmer days, after the martyrs' fires in Smithfield under Mary. These were the times of the splendors of Kenilworth Castle, so graphically described by Sir Walter Scott; the times of Sir Walter Raleigh, who founded the Colony of Virginia and introduced into England the smoking of tobacco and the culture of the potato.

This was the time, too, of Sir Francis Drake, the great explorer, the "merchant adventurer," who held that to spoil and burn the Spanish settlements on the shores of the New World, or to capture and put them to ransom, and to waylay the Spanish galleons, laden with gold and silver from the mines of Mexico, were acts, not only most profitable, but really meritorious and virtuous proceedings. The struggles with Spain, culminating in the defeat of the Spanish Armada in 1588, were sequels to these events.

William Shakespeare is another celebrity of this period whose birthplace still remains, an example of the village architecture of the time that is visited by about 30,000 people annually.

"Monopolies" took their rise in these times, and among their number was the "Charter of Privileges" granted in 1600 to the recently formed "Company of London Merchants trading in the East Indies." Thus was founded the famous "East India Company" from which has developed the present British Empire in India. These salient historic facts are laid before the reader to associate in his mind the then prevailing style of building known as "Tudor" with the political and social state of the country; that the ear-marks so easily recognized on the domestic buildings of the period may, as an open book, reveal the life and manners of the people by whom they were erected.

With the close of the Perpendicular period at the end of the fifteenth century, the erection of ecclesiastical buildings ceased in England and domestic building alone occupied the architectural field.

Legal enactments were brought into operation and vigorously enforced, for the suppression of the custom of previous ages of maintaining bodies of military retainers and for the curtailment of the aggressive power of the older nobles. The feudal system had passed away; the days of chivalry were dead. The march of education had taught that violence, conquest and spoliation were not necessarily the only and the highest aims of life. A love of peace, culture and prosperity was abroad in the land. Commercial importance was asserting itself. The accumulation of wealth expended itself on more profuse hospitality; equipages and retinue, though reduced in extent, increased in magnificence and the luxuries of life became more appreciated.

The distribution of the wealth of the monasteries; the spoils of the piratical warfare on Spain and the Netherlands (then under Spanish rule); the new-born trade with the Indies, all tended to accelerate this social development and create the demand for those stately mansions and more modest dwellings that are scattered throughout the land as historic milestones.

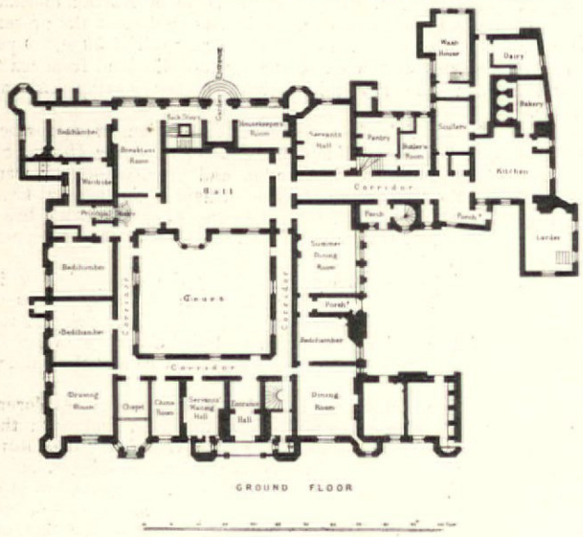
The lay proprietors into whose hands had passed the monastic

[1] Continued from No. 1369, page 94.

[2] Among these was Torregiano, a fellow-worker with Michael Angelo, who, in retaliation for a sneering remark by the latter, struck him in the face, breaking his nose and disfiguring him for life.

estates at their confiscation, either by gift or purchase, found themselves, *ipso facto*, the possessors of the churches incident to the numerous parishes included in these estates. They became, in fact, "lay-rectors," an altogether new element in the State.

These churches had beforetime been served from the monasteries

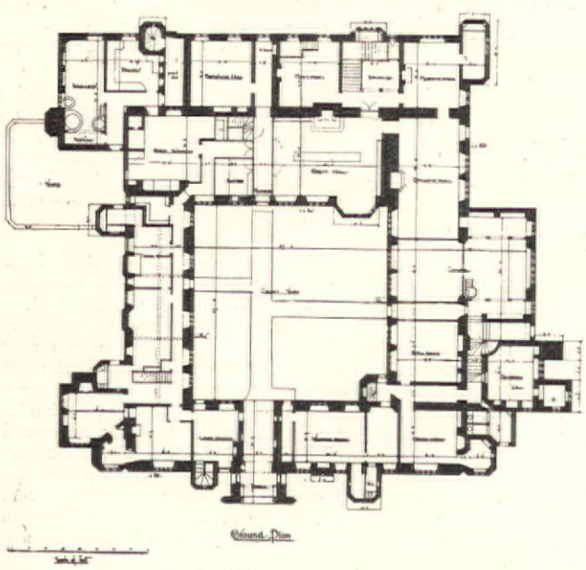


Hengrave Hall, Suffolk.

which collected the tythes and dues. These lay proprietors continued to collect the rectorial dues as part of the income pertaining to the estate and relegated their religious obligations to a deputy or vicar to whom they paid a fixed stipend. Hence, we find the many new vicarages, parsonages and granges of that period erected contiguous to the churches of earlier date.

Then again with this "dissolution of the monasteries" there came a great change in the agricultural class. This enormous acreage of land, more or less under cultivation, yielding an annual rent-roll estimated at one million sterling (say $5,000,000) was rapidly thrown upon the market and bought up, at low prices, by any one who had the capital to do so. This "capitalist" class (another new feature of the times) was made up of merchants, tradesmen and the more thrifty of the franklins and yeomen who, finding themselves proprietors of more land than they could cultivate, let it off to others who were able and willing to pay a rent for its use in coin instead of service, a matter of obvious mutual advantage. Thus sprang up a newer landlord class, who lived upon the investment of their savings or accumulated wealth, and the agricultural class, or tenant-farmers, who cultivated the soil. These, too, built themselves dwellings according to their means, in stone, stone and brick or half-timber, many of which remain to this day scattered over the old monastic estates, often forming the nucleus of the hamlets or villages grouped around the churches of still older date.

These social changes, brought about by the great political events of the time, were the moving causes which led to the wonderful



Compton Wyngate, Warwickshire.

building activity of the time, and developed that tendency to the ornate that marked the Domestic Architecture in England during this particular period of the Middle Ages.

The typical house of the period is still surrounded by a moat, but spanned by a permanent bridge, usually of stone, in place of the drawbridge of earlier days. The visitor, on passing beneath the open entrance-archway, finds himself in a quadrangular courtyard, often planted with yew-trees (as at Speke Hall), in the centre of which stands the sundial of quaint design. The house frequently only occupied three sides of the quadrangle, more or less ⊓ shaped in plan, the fourth side being enclosed with a wall, with the gateway in the centre.

Opposite the gateway would be found the entrance, with the great hall to one side of it with its characteristic bay-window of many stories. The hall was entered from a passage formed by an ornamental screen of oak carrying the minstrels' gallery, as at Parham, Hampton Court, etc. Some of these halls had open-timber roofs, as at Hampton Court, Eltham, Hardwicke and Wollaston; others, again, of later date, had flat panelled timber ceilings, as at Rufford, Charter House and Bagully. The great projecting bay-window, furnished with a fixed seat, gave a certain seclusion almost spacious enough for a withdrawing-room. The large open fireplace with its ingle-nook became a centre round which legends and tales of adventure were told over the blazing logs when the storms blew cold without.

The common, or great, hall, which had reached its utmost development and magnificence in the later Perpendicular and Early Tudor periods, began to decline after the time of Henry VIII, the entrance-hall, often of great dignity, and the wainscoted parlor, with its magnificent chimneypiece, taking its place in the newer buildings.

A small hall will be found, entered from the dais end, in which the family dined in private, or when the great hall was cold and draughty in the winter. It was a pleasant place, too, in summer, for it had its bay-window projecting into the garden and its private exit, as at Ordsall.

The ladies' withdrawing-room will be found close at hand. This became a feature of considerable elegance as times progressed, decorated with elaborate plaster ceilings, divided up into panels with

The Inner Court: Houghton Tower, Lancashire.

carved oak beams, the centres of the panels enriched with fruit and flowers, modelled in high-relief, as at Speke Hall, Astley Hall, etc.

In the older houses we found the rooms led mostly one into the other, but, as privacy became more appreciated, passages appeared and developed into corridors. See plan of Compton Wyngate.

The largest apartment on the upper floor was the gallery, an entirely new feature, which may be described as a magnificent amplification of the corridor into a separate state apartment, for the more particular display of works of art and of the family portraits, the pride of ancestry. At Astley Hall this chamber is panelled in oak from floor to ceiling, and the quaint high-backed chairs and carved presses or cabinets still stand against the walls. The most interesting piece of furniture in this room is the ancient massive Shrove-groat table. "Hit him down, Bardolph, like a Shrove-groat shilling," says Shakespeare in alluding to the game that was played upon it. Many of these pieces of panelling and furniture were the spoils of Flanders, France and Scotland during the preceding wars.[1]

The approach to this gallery was by the grand staircase, another feature that at this period developed the most stately proportions, with its boldly carved newels and balusters, its broad and easy treads and spacious landings. These features, which have the distinctive feeling of Italian influence (found in the Roman palaces), gradually became the most marked characteristics of the period.

The bedchambers of the wealthy were furnished in sumptuous style. Queen Elizabeth was fond of comfort and display, as may be gathered from a wardrobe-warrant, dated 1581, at the British Museum. It orders for the Queen's use a bedstead of walnut-tree, richly carved, painted and gilded. The selour, tester and valance were of cloth-of-silver figured with velvet, lined with changeable taffeta and deeply fringed with Venice gold, silver and silk. The curtains were of tapestry, the head-piece of crimson satin edged with passamanque

[1] Many of these old family relics are being used in the houses of the present day, some worked in as hall furniture, over-mantels in dining-rooms and libraries, particularly in new houses erected to replace as residences those of this period, as at Pirton Hall (replacing the old moated grange), Bramingham Shot and others, the works of the author.

of crimson silk and decorated with six plumes containing seven dozen ostrich feathers. The counterpoint was of orange-colored satin, quilted with cut-work of cloths of gold and silver, etc.

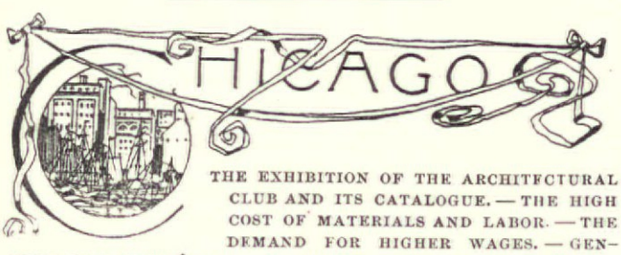
Mention is often made of the priest's rooms; the chaplain not only ministered in religion, but was also the instructor of the youth of the family, the custodian of such library as the owner possessed, and, as we find related in many historical novels dealing with these periods, played no small part in the domestic history of the times.

Another feature we find in the typical house of the period that came more into prominent use in the later Jacobean times is the hiding-places and secret passages in the walls, access to which was obtained by cunningly concealed sliding panels in the wainscoting of the rooms. We find in records of the sixteenth and seventeenth centuries frequent reference to the remains of vaults, passages and secret stairs (as at Woodstock), giving access to concealed chambers secured by gates, heavy doors, etc. A good example may be found in Moreton Hall, where two apartments are entered by a sliding panel, and by a trap-door in the floor fugitives were enabled to escape and reach the farthest parts of the house. It is not surprising that such houses should become the centres around which stories and legends have been woven, and whose panelled chambers and hiding-places should be peopled with the ghosts of departed heroes.

The farm-buildings of these houses stood more or less apart, the barn being the great feature and built with nave and aisles. We also find dairies, stables and provision for falconry, and, particularly in Yorkshire, large stone towers erected for pigeon-cotes, as at Barnboro, near Doncaster.

The greater portion of Haddon Hall is of this period, the chapel and banqueting-hall being earlier (1452), the towers and turrets standing up above the full foliage of summer in picturesque outline. Almost every great English home of this period is memorable and dear to the imagination for the sake of some one person or some one romantic incident, and all Haddon is fragrant with the memory of Dorothy Vernon. We have her postern from which she eloped, her walk, her rooms, her terrace, etc. THOMAS C. SORBY.

[To be continued.]



THE EXHIBITION OF THE ARCHITECTURAL CLUB AND ITS CATALOGUE. — THE HIGH COST OF MATERIALS AND LABOR. — THE DEMAND FOR HIGHER WAGES. — GENERAL SOOY SMITH'S WARNING ABOUT STEEL-SKELETON BUILDINGS. — THE "LAKE-FRONT" QUESTION.

THE Chicago Architectural Club is now holding its annual Exhibition at the Art Institute. The Exhibition fills three or four galleries and is in many ways creditable, though there are some features which are questionable for a general exhibition.

On entering the first large gallery, the most striking design in the room is the large drawing entitled the "Beacon of Progress, a monument," to quote from the catalogue, "typifying the apotheosis of American civilization, to be erected on the site of the World's Fair at Chicago." The statement that it is to be erected is hardly borne out by the facts of the case, though could it be accomplished it certainly would be a very remarkable and imposing production. At the time of the first publication of the drawings here in Chicago, the scheme was commented upon in these letters. The design, made by M. Despradelle, of Boston, both in its detail and entirety, is a very impressive piece of work. One appreciates it to a much greater extent when the original drawings are seen, the details especially bringing out the perfection of its huge proportions. That it ever can be carried out seems more than doubtful, as, for the execution of such a purely monumental piece of work, there would need be a Pharaoh, with his command of millions of both men and money. It, however, should appear as a blessing that the erection of such mammoth toys is now an impossibility; but we are all grown children at heart, as much now as in the days of Assyrian or Egyptian despots, and to the average man such grandeur and size cannot help but appeal.

While the list of exhibitors shows nearly as many outside of Chicago as in, the impression of the Exhibition is that it is given over, not only to Chicago, but to the less-important class of work of the younger men, who chiefly compose the Club membership. In fact, in many ways the exhibits brought most into prominence are of the arts-and-crafts type, rather than the strictly architectural class of designs. Moreover, the few examples of large and serious work that are exhibited seem to have been relegated into the background as much as possible. Nor is there illustrated a single example of the larger work that must of necessity endure long after that of a smaller nature has been forgotten.

Collected under the banner of Mr. Frank L. Wright, doubtless, most of the designs bearing his hall-mark, one of the smaller galleries is given up entirely to his exhibit. From the standpoint of professional ethics it seems questionable whether such a pronounced personal exhibit should have its place in a general architectural exhibition, as it certainly smacks of advertising more than anything else. Having selected one of the small rooms, with a door for entrance and one for exit directly opposite each other, a low partitition is run across from one door to the other, forming a distinct room. The color-scheme of this small division is very charming. Warm light browns and grays are combined, the walls being some brownish burlap banded with strips of some soft-finished wood. The exhibited designs on the walls are all framed to harmonize with the general color-scheme. Brown-leather covers stretch across desks and tables, on which dull copper vases hold effective bunches of gray milkweed pods, brown grasses, teazles, etc. Tall copper and bronze vases in the style of "L'Art Nouveau" hold slender brown seed-cups of some last year's plants; bits of colored and leaded glass, a marble font of good design, a bronze figure, chairs and tables from Mr. Wright's own house, all have a place in this room. This is all very well as far as it goes, and it certainly is *pretty*, almost "too pretty," as Mr. Raffaelli has put it, for such a place as this. Why in an architectural exhibit, the chief one in Chicago for the year, why should Mr. Wright's tables and chairs, and his teazles and milkweeds and pine-branches cover so much space? When one sees the seriously beautiful work, even in domestic architecture, that is being done in other parts of our country, notably in the East, one is ashamed of the trivial spirit that is abroad here among us. There is a set of younger men here in Chicago who foster all this sort of thing. They have among them men with the artistic spirit and feeling, but their aim seems to be always to strive for the semi-grotesque, the catchy. Their compositions lack the best principles of honest design. Their aim seems to be to impress upon the beholder the belief that they are so filled with artistic inspirations and ideas that the flood cannot be held back for a minute, but must be dashed down onto paper as fast as ink or lead can carry it. There *is* a certain dash about it. These men treat the world like one huge studio, but how will these things look, say, even twenty years from now? Like a dusty studio from which the life has gone. There certainly will be no acquired dignity born of time. The designs hardly amount to designs and the execution is usually so extremely cheap that one questions the honesty of the whole thing. Not only in the profession but out of it do people here constantly take this short cut, which they think leads to perfection in art. It is a dangerous thing and one which will hurt the best interests of art and architecture in the section of country where it most flourishes. Originality, tempered with honest endeavor and careful thought and work, gives a fine flavor, one that the more it prevails in a community just so much better is it for that community; but careless self-sufficiency, that is a different thing.

There have been two notably fine houses finished on the North Side in Chicago this year, one a beautiful Colonial on Wellington Avenue, the other an equally good French Renaissance on North State Street. Only one of these houses appears at the Exhibition and that only in one form, somewhat overshadowed in spirit by teazles and pine-branches, and this is the only showing, though they both are unquestionably the strongest examples of domestic architecture here for several years.

The catalogue this year, as in 1901, is quite an imposing affair. On some separate leaves, laid in the book, is the alphabetical list of exhibitors, while the bulk of the book is given over to illustrate selections taken from the material of the exhibit.

While supposedly free from advertisement, and for this purpose published by contributions solicited from architects and others interested in the Club, it must be recognized by nearly every one that this catalogue is nothing but a huge advertisement for a few exhibitors. Aside from all questions of professional ethics on advertising, which the Club committee would have been wise to have considered, it seems decidedly impolitic for the architects themselves to have permitted it. The works of different men are placed in the catalogue in groups in the reproductions of drawings and photographs of actual buildings and details. This is generally done quite unostentatiously, but when Mr. Frank Wright's portion is reached, we are introduced to his fourteen pages with a title-page effect in which is the inscription, "The Work of Frank Lloyd Wright." A Wright chair, vases and the bronze figure, before alluded to, and the usual architectural jetsam compose the material of the title-page composition.

To glance at the catalogue one would think that this "L'Art Nouveau" of ours was the only manner of existence in architecture here, and it is a positive relief to turn to some of Mr. Sullivan's charming designs, a cast-iron grille arc-lamp for one thing, and some beautiful details of his in the large building for Gaga Brothers on Michigan Avenue.

The general building prospects in Chicago are not as bright as they seemed a few months ago. The number of large downtown buildings is considerable, as enumerated in our last letter. The amount spent on each building is, of course, large, and the sum thus spent brings up the total aggregate of money put into building-interest into large figures. This would seem to indicate a greater number of buildings to be erected, or in the process of construction, than there really is. A good deal of work is reported among the factory class of building.

The Parmlee Express Company is about to erect new quarters for itself on the West Side. Plans have just been completed for a three-story stable and wagon-depot to cost in the neighborhood of $200,000. The first story will be devoted to the storage of omnibuses and wagons, the second is for horses, and the third for feed and grain. It is the intention to make it quite a model stable, and the architect, Mr. M. L. Beers, is said to be giving it especial thought.

Comparatively little is being done in domestic architecture directly in the city, and the tendency is all to the suburbs for prominent houses. The North Shore is by far the most attractive suburban section, and a large number of fine residences have been erected through this district the past year.

Evanston, the largest town in this section, has had built a unique little building in its new Domestic Science School, the gift of two public-spirited citizens. It is a one-story building, rather Classic in character, the material used being buff brick and gray stone. The north room is given up to the boys and manual training, while the girls and domestic science fill up the remaining space. The girls' quarters are somewhat picturesque in blue and black, while the boys' training-room makes no pretence at decoration.

It is to be hoped that this spring no serious labor troubles and strikes will arise. The cost of both labor and material is very high, having increased fully thirty-five per cent over what it was six years ago. The demand for workmen of all kinds, whether skilled or unskilled, is very great, and, consequently, builders are compelled to pay wages which appear excessive. It is reported that nearly all the trades in building-lines will ask for an advance this spring. The brick-masons, whose union is especially strong and well organized here, inaugurated the movement, and it is unnecessary to state that other trades have followed their example. The bricklayers have asked for sixty cents an hour after May 1, while the mosaic-tile and encaustic workers will demand the same wages, with thirty-five cents for helpers. According to the agreement made a year ago with the carpenters, their wages have been since the first of April forty-five cents an hour, instead of forty-two and a half. Ordinary laborers are now receiving twenty-five and twenty-eight cents an hour, but after May 1, they will demand thirty.

Periodically, Gen. William Sooy Smith, or some one else, comes along and tells us our sky-scrapers are in danger. General Smith, at a banquet of the Real-estate Board, has warned us that unless the iron and steel used in the construction is properly protected by concrete, corrosion will take place and a collapse of the building follow. Though this sounds like an ominous warning, Chicago goes merrily on, and hopes the steel is protected. General Smith says the attempt to cover steel with perishable paint is worse than useless. "The ordinary corrosion of steel," says General Smith, "takes place at the rate of one one-hundredth of an inch a year where metal is exposed to moisture, wetting and drying. This amounts to one-tenth of an inch in ten years. In the case of a steel column when it corrodes both inside and outside at this rate, the diminution in thickness would be two-tenths, or one-fifth, of an inch in ten years. In twenty years it would be two-fifths of an inch. The columns in our steel buildings would not support the loads they carry safely, with any such diminution in the thickness of their metals. It is not to be feared that the corrosion which actually does take place would reach that amount uniformly over an entire building, but there is a danger, the one to which I allude, resulting from rapid corrosion at one or more vital points in our great steel structures." Several men were interviewed who are connected with firms doing much of the work of the large office-buildings and they seemed to take the warning calmly.

With the opening of spring and with the desire to "tidy-up" every inch of available ground, the ever-recurring question of the Lake-front returns. This time something is going to be done besides talk. Some of the property-owners facing on the tract began to realize that probably not in their life-time would the grand scheme be carried out, which will incorporate the Lake-front into a part of a fine boulevard system. Consequently, money has been raised by these property-owners to the amount of $15,000, and the unsightly tract just north of the Art Institute and south of the present temporary post-office is to be taken in hand. Plans have been made for its future laying-out, and though, as they were published, they did not appear to contain any very unusual features, still even the most commonplace arrangement would be infinitely better than the present mud and cinders.

STRUCTURAL COLOR-DECORATION OF THE INTERIOR OF PUBLIC BUILDINGS.[1] — I.

I THINK that before I presume to say anything on this subject it is due to my audience to offer some explanation as to how I find myself, an architect, in this position. When I was most courteously asked if I would read a paper before the section on this subject, I felt at once that this was really a painter's subject, and that it would be better if a painter — one of those who we know are not only wishing to paint in public buildings, but who are also very capable of performance — should be asked to deal with it. But reflection reminded me that it is an architect's subject too; one common to architects and to painters, one both must be interested in, and one both must have at heart; consequently, though with misgivings as to my capability to say anything worthy of its importance, I could not for a moment refuse on the ground that it had nothing to do with me. It is a subject which by practice, and by study, an architect should try to make his own, and which draws him into close amity with the workers in the other crafts. None gives them better the opportunity of working together, and proving the truth of Stevens's words, "I know but one art." We know how close this union was in the past, and what immortal works it accomplished, and though the association is not now so frequent, there are, at any rate, signs that the ancient sympathy has revived, and is bearing fruit, small the yield perhaps now, but soon, we may hope, an hundredfold. This sympathy, once so full of life, has slept of late, awaking fitfully at times, but ready always to burst out into fullest life when demand is made.

The subject which we are to discuss is a wide one, for it includes the consideration of a large number of building methods, and of various schemes of decoration. It may, I think, be said to embrace those many systems of decoration which by their nature are one with a building, or an actual part of it. It does not include those likewise numerous forms of decoration which are easily removed from the building which they are intended to adorn.

For instance, the Palazzo Pubblico at Siena with its large frescos illustrating good and bad government, intended to instruct the Sienese in that essential matter, comes within our view; but the great council-hall at Venice, on the walls of which are stretched the largest canvases in the world, including the "Paradiso" of Tintoret, however much we may admire them, does not. Nor does the modern council-chamber, poorly decorated with a portrait or two of a former or present mayor, except as a reason for lamentation and hope of change. While, therefore, the subject is a wide one, it has strict limits which it will be necessary to observe.

Perhaps it would be as well for me to define a little more clearly what I consider these limits to be. The title "Structural Color-decoration of the Interior of Public Buildings" makes me at once think of two kinds of public buildings, namely, first, of those which have been constructed of such materials as to carry out a previously conceived scheme of color-decoration; it implies that the floors, the walls and the roofs have been constructed of materials which make up a color-effect.

Then, secondly, I think of those public buildings which, after their completion in the rough, have been decorated in color, in a manner which makes that color one with the materials. Therefore, we may consider our subject in two parts or divisions: —

1. Those buildings whose actual materials form a color-scheme, such, we will say, as the Duomo at Siena.

2. Those buildings which on their completion have been decorated in color in a manner which makes that color one with the materials of the building, such as S. Francesco at Assisi, or the Borgia apartments in the Vatican.

Just as there is no hard or fast rule in art or in her methods, so do these two kinds of decoration overlap, and react upon one another, for, of course, one building may represent both.

It is hardly necessary, perhaps, to define for our purpose a public building. A cathedral, a church, a parliament-house, a town-hall, a meeting-hall, a theatre, a railway-station, all come within our view and open a wide field for consideration, wider, I fear, than the time at our disposal will permit us to consider.

The methods of decoration possible under the two main heads I have named are as various as the types of building I have suggested. The colors of the stone and wood used, fresco, *tempera*, oil-paint, plaster-work, sgraffito, mosaic, tile-work — all have a claim to a place in our thoughts.

Unfortunately, we have to realize that although this wealth of art methods is open to our use, and though we have intimate knowledge of its processes, there are but few public buildings in this country which have any structural color-decoration, and that there is but little demand from the public for works of the kind. It is a remarkable fact that since the sixteenth century in England the practice of decorating in color all our buildings, both public and private, as a natural and expected action, has declined. It is as if our countrymen, who lavished color in cathedral and castle during the centuries preceding the Reformation, had suddenly lost all hearty desire to beautify their buildings in this particular way. We know that England was not behindhand in knowledge of the decorative arts. The remains of the noble craftsmanship in painting and sculpture of the thirteenth and fourteenth centuries go to prove that Englishmen knew how to paint and to carve. The late Professor Middleton has said of English art from 1260 to 1320: —

"The painting of England was unequalled by that of any other country; even in Italy Cimabue and his associates were still laboring in the fetters of Byzantine conventionalism, and produced no works which for jewel-like color and grace of form were quite equal to the painting under Edward the First."

Encouraged by kings such as Henry III, and by the Church, English artists decorated Canterbury, Westminster, Salisbury and countless buildings throughout the land, but the civil wars, the coming of the Renaissance from abroad, the fall of the Church, and the growth of Puritan feeling, seemed to paralyze the development of native decorative art. No Pinturicchio arose here as in Italy, no Raphael to work with the architects in the adornment of public buildings. The Renaissance, instead of adding to our confidence and energy, seemed to condemn us as insular, to be without artistic knowledge, unworthy to paint frescos. Little belief in our powers was shown by those in high places, by those able to commission and encourage. Was sculpture needed, or painting, the artists must come from abroad. Torregiano must make the King's tomb, later Rubens alone can paint the roof at Whitehall, just as Vandyck must paint the portraits. Verrio must paint the ceilings and walls at Hampton Court. Though, through it all, there were English painters, whose works we know, and many art craftsmen, the English artist was eclipsed by the superior skill of the foreigner. With the advent

[1] A paper by Gerald C. Horsley read before the Society of Arts, and published in the *Journal* of the Society.

of Wren, the great English master, we find our countrymen again employed in important work, Streater, in the Sheldonian, at Oxford, and, still later, Sir James Thornhill, at St. Paul's, and at Greenwich.

It has been said that the revival of letters 400 years ago, made it no longer so necessary that the walls of public buildings should furnish a literature for the people, and thus a great incentive to noble, historical and allegorical painting died. Together with the sciences, the painters became learned and conscious. The naïveté of the earlier masters changed to greater care in exactness of representation, but with the old impossibility of the human race to do all things well and perfectly at one and the same time, their works lacked the simplicity and dignity of the earlier period. Architecture thought more of itself and less of the other arts which had previously combined with it to form an organic whole. If she used painting, it was more as a mistress employs a handmaid, and less as an equal coöperating with an equal, and painting apparently would have it so. Instead of covering wall-surfaces with representations of noble deeds by great men, or pictures portraying the mightiness of virtue and the baseness of evil, as in the days of Giotto and Lorrenzetti, she wasted her powers, her perfect knowledge of technique, in extravagant flatteries of her employers, such scenes as we see Rubens painted for Marie de Medicis, the "Apotheosis" of James at Whitehall, and the foolish scene of "Olympus," by Verrio, at Hampton Court. Can we wonder, when we see the purpose of painting reduced to these inanities, that the link uniting her to the great art of architecture would not bear the strain, or that we should have seen, as we have seen, painting and architecture widely separated, the one perfecting herself at the easel, and the other working experiments in the different styles?

We cannot imagine a more half-hearted, or more selfish condition of things, or one more contrary to the spirit of the great days of art. It is, at any rate, to the credit of English architects that they have all along recognized — and with much fulness of late — the harmfulness of the position.

On the other hand, we have also to notice that the Continent has never lost in the same degree as ourselves its interest or delight in the use of color-decoration. Changes not dissimilar to our own have taken place, but the arts of architecture and painting never lost touch one with the other as they did here. In Italy to this day a color-scheme in a new building has a prominent place. In France, a church, a *mairie*, or a theatre, even a railway-station,[1] is not considered complete until it is painted in *tempera* or with canvases, *maroufle*, so that they form part of the building. Such conditions as these may also be found in Germany and Austria. England alone seems, with but few exceptions, to disregard color as a necessary element of beauty in the designs of the interior of her public buildings.

What these exceptions are we may presently consider, but it is time to discuss the two divisions I have just mentioned, particularly with some regard to our work and practice at the present time: *first*, those buildings whose actual materials form a color-scheme. This is a method of decoration which was more in favor with the last generation of art-workers than it is with us at the present day. We are reminded of the buildings of the "Gothic revival," of the works of Butterfield and Street.

These buildings were the result, no doubt, of visits to Italy, where their prototypes may be found, also of a study of our own Gothic period, when a certain amount of parti-colored wall-work was done, brought to us by the mediæval current of art practice from east to west. Modern churches like All Saints', Margaret Street, and Keble College Chapel, by Butterfield, and the church in Garden Street, Vauxhall, by Street, are buildings of this type.

In process of time we seem to have largely passed away from this kind of work; it does not now seem so well worth doing, the results obtained were often cold-looking, harsh and mechanical, owing perhaps to the mathematical accuracy of modern building methods, but there was a principle underlying it all, one of value which cannot be lightly dismissed. We must remember, that when Butterfield did this work it was a great achievement, a launching out into new methods, a deliberate attempt at a human expression in art, and a clean break away from the (to him) cold and formal, dull and vacuous, interiors of 1845. Butterfield, in "All Saints'," has done this, his first essay in the manner, with consummate skill and largeness of feeling, better than at any later time, and better than any of his imitators, and there were many who followed his lead. Few artists ever took such great pains or had such great gifts as William Butterfield. We must not think that he introduced this colored work with the sole intention of breaking-up the appearance of the wall-surface. This was clearly not his main idea. With the "true principles" of the Neo-Gothic architect — and here I think we have the principle underlying so much of this work — his aim was to get a permanent wall-decoration, one which would outlast the usually improperly made plaster wall-covering. He recognized the difficulty and expense of securing any form of painted wall-decoration, also the deleterious effects upon any painted surface of the fumes from gas-lights and oil-lamps, and the evilly-charged atmosphere of London and our great cities. He set himself, therefore, to produce something which was suitable, lasting, and easily kept clean. He did this admirably. Take, for instance, the wall-surface at All Saints', Margaret Street. First, there is a dado of full color some five feet high of tiles; above, large scenes from the New Testament painted on tiles. Above the arches of the nave-arcade the wall-surface is stone, inlaid with bold patterning in tiles and dark inlay. On the east wall only is there any painting. Here are frescos by Dyce in panels spaced between margins of alabaster. The roofs are vaulted and painted in the chancel, and painted wood in the nave. With the exception of the pictures on the east wall there is not a scrap of plaster in the church, and no one will deny that the scheme is interesting and good. In Keble Chapel there is a very similar scheme, but in materials more precious, as befits a college chapel of such importance. Here the lower part of the wall has an arcading of stone, with the spandrels formed of colored bricks. Above, at a height of some 10 feet from the floor, are pictures, the subjects from the sacred history, in mosaic, and framed in stone. The pictures form a large and striking frieze running round the chapel; above it are the windows filled with painted glass, at some height, therefore, from the floor. Between and above the windows are more bands of colored brick. The roof is vaulted, painted to represent stone. Here again, therefore, except in the painted roof, the ground of which I suspect is in well-made plaster, there is no plaster used, and the whole effect is one of great dignity. To our eyes nowadays such a method as this would require to be carried out on the broadest and simplest lines; we should also demand that the materials should be worthy. The black, white, and yellow bricks of fifty years ago have few charms for us now.

The system of alternations of color in a wall-surface, which, no doubt, had its origin — so much as came to us from the East — in the ancient Chaldæan and Egyptian worship of the universe, when by building their temples and pyramids in colored stripes or courses, in due sequence and tints, they commemorated the heavenly spheres, fits in with the natural demand of the eye, which welcomes and recognizes the propriety of variety in color. It is open to us, therefore, to appropriately use the differently colored stones we have, or our own native marble, while, thanks to the discovery and reopening of some of the old Greek and African marble quarries by men of energy and foresight like Mr. Samuel Brindley, of Messrs. Farmer & Brindley, ancient sources of supply are no longer closed to us. So long as we arrange the materials at our hand, be they of clay or stone, with breadth and simplicity, we shall be treating them with the dignity they deserve; and in buildings of importance we shall, I think, be treating ourselves with greater consideration if we invest our patterns with some meaning and intention.

Such principles as these, common to all forms of art, seem to be especially brought into mind when thinking of this form of treatment of a wall-surface. In passing I may point to the Baptistery of Florence, San Miniato at Florence, the Church of the Miracoli at Venice, some late Roman examples at Ravenna, as being particularly successful examples of the use of marble in this connection. The cathedrals of Orvieto and Siena are direct descendants of the striped work of the Saracen builders, a method of building common in the East to this day, and dating, as I have said, from her immemorial past.

Tho second division of our subject — "Those buildings which, on their completion, have been decorated in color in a manner which makes that color one with the materials of the building," offers a larger field for examination. It brings us into touch with the methods employed by our fellow-artists, the painters, and other art-workers, and into notice the conditions which govern the employment of artists in these matters. I ventured to point out just now the different state of things 400 years ago in this country, compared with the present time. How that then nothing was more natural in most communities than a wide employment of painters and workers in the arts in the decoration of public buildings. The history of the past, and the examples remaining to us make this clear. What a contrast presents itself in our own time! Who, for instance, can read the story of the preparations for decorating the Houses of Parliament, fifty or sixty years ago, without amazement and astonishment at the ignorance of, and want of confidence in, the capability of the painters of that time by those in high authority. For some twenty years a Royal Commission was in existence, to consider and decide upon the best means of painting certain panels and rooms in the new Palace of Westminster. They instituted open competitions, invited cartoons, called for samples of painting in fresco. They doled out a few commissions. The expense incurred in preparing for these competitions and trials in painting must have brought many artists to the verge of ruin, and the many delays and slow procedure disheartened and crushed the spirit of all. If anyone wishes to read the sad story of these years, let me refer him to Redgrave's "*Century of Painters*," where the whole history is set forth by one who lived during the time, and knew it well. It may be that the government of our country is too complex and vast an institution to see the advantage of departing from the competition-system, and to trust with commissions artists whose works and capabilities are known, the execution of which would add to the intellectual and artistic output of the country. The few examples we have of such a departure have been signal successes. I may refer, as an instance, to the employment of the late Lord Leighton in the frescos "Arts of War" and "Arts of Peace," at the South Kensington Museum.

Fortunately, the experience of the Houses of Parliament Commission I have referred to has served as a warning throughout the country to municipalities and to individuals; and it has been, no doubt, easier for municipal councils, who have so much power in their hands, to foster and encourage the arts of the country, and with their less cumbrous governing machinery, to avoid the many mistakes it is possible to make in the fit decoration of a building of

[1] The new Gare d'Orleans, at Paris, has two large wall-paintings of "Biarritz" and "The Loire" in the waiting-hall.

importance. This is evident by the conspicuous success which has attended the efforts of some of the municipalities of the country. Manchester is most fortunate in having commissioned Ford Madox Brown to paint the scenes from her history in panels in her Town-hall. Glasgow is employing some of her own sons, Messrs. Henry, Lavery, Walton, and Roche, in her city buildings. The Corporation of Liverpool, acting wisely on the advice of their architect, has commissioned Mr. Charles Furse to paint the pendentives of its large dome, illustrating scenes from the commercial greatness of the city. Birmingham has commissioned some of the students of her Municipal School of Art to paint scenes commemorating her history in panels in the Town-hall. The Corporation of Colchester also, in the new Town-hall, on the advice of their architect, Mr. Belcher, is employing Mr. Charles Baskett to decorate the Council-chamber and Moot-hall, under his supervision and with his assistance. In London, in our own Royal Exchange, the Corporation of the City of London, together with some of the great City Companies, have commissioned artists to paint the panels of the ambulatory.

For some years past the municipalities of our towns have been fostering a love and appreciation for our arts by buying pictures and placing them in suitable galleries. This virtue of acquiring beautiful things has now been supplemented by giving commissions for mural painting. In the placing of these commissions, we have the greatest hope and encouragement for the future, and with the increase of the municipal councils which is taking place in our midst, we may look to see full advantage taken of the opportunities the public buildings present for the employment of artists of proved power and attainment, to the advantage of the people of this country. With this hope in our hearts, we may consider, with greater interest, certain of the methods of work which at the present time are in use.

NOTES AND CLIPPINGS

THE MCCLELLAN STATUE COMPETITION.— Twenty-nine sculptors are said to have signified their intention to submit designs for the statue of General McClellan, which is to be erected in Washington. — *Exchange.*

A VESSEL IN COURSE OF CONSTRUCTION, IS A STRUCTURE. — The question before the Appellate Division of the Supreme Court in the case of Frank Chaffee against the Union Dry Dock Company was whether a vessel in the course of construction in a shipyard is a "structure" within the meaning of that part of the labor-law relating to the duty of the master in erecting scaffolds about buildings in the course of erection. The plaintiff received injuries through the fall of a scaffold built around a vessel on which he was working. A judgment in his favor is affirmed, the Court saying it readily concludes that the vessel in question was a structure within the meaning of the statute. The purpose of the law, the Court says, was to ensure greater protection and security for workmen, and to prevent falls by reason of defective scaffolds. "It was an entirely immaterial circumstance before this general purpose," says Justice Hiscock, "whether the scaffold should happen to be around a house, a barn, a vessel, or a flag-pole. If it fell 40 feet, the man upon it would be injured in one case as readily as in the other, and it was against that injury that the Legislature sought to guard by imposing additional responsibilities upon the employer in favor of the employé. The word 'structure,' measured by its derivation, means something which is arranged, built, or constructed. Bouvier defines it to mean that which is built or constructed. It has been judicially construed, among other things, to include poles planted in the ground and connected together by wires and insulators." — *N. Y. Times.*

AN ANCIENT CITY OF THE ZAPOTECAS DISCOVERED. — Leopoldo Batres, Conservator of Archæological Monuments in Mexico, has exhumed an ancient city of the Zapotecas in the State of Oaxaca. In its centre is a grand plaza, and rising to the north of the plaza are terraces, on which are founded two great temples, while in the centre of the plaza itself are two massive mausoleums in which the priests of the temples were buried. On opposite sides of the public square there are also twelve smaller shrines, six on either hand, all supported by heavy columns of basalt covered with hieroglyphic inscriptions in bas-relief. In the temples the history of the people was found inscribed in the language of the Zapotecas upon fifty tablets of stone. So much of a surprisingly rare historic import has already been found that Mr. Batres will ask the Government for more men to be put to the work of exhuming and restoring the buildings of the long buried city. — *N. Y. Tribune.*

THE SPEED OF UNDERGROUND STREAMS. — A recent and interesting development in the work of the Division of Hydrography of the United States Geological Survey is the study of the flow of water under ground. In many localities the water which finds its way beneath the surface is of considerable economic value, but little has hitherto been known regarding its speed and the manner of its flow. During the last season the Geological Survey has been engaged in a series of preliminary studies under Prof. C. S. Slichter of the University of Wisconsin of the underflow in the sands of the Arkansas River. The method of investigation is entirely new; two test wells are driven and electrically connected. Into the upstream well is placed an electrolyte, or dissolvable substance, which affects the electric current. This electrolyte enters the underground water at the first well and gradually passes down stream to the second. In the electrical circuit between the two wells the needle of an instrument records its approach, and is strongly affected by its final arrival. By watching the increasing deflection of the needle it is possible to trace the movement of the water from the beginning of the experiment and to study the variations of its flow. In the experiments on the Arkansas River the rate of the underflow was found to be from 3 to 15 feet per day. — *N. Y. Evening Post.*

ACETYLENE GENERATORS TEST. — The increasing use of acetylene generators in this country lends interest to the tests lately made by British experts to establish the conditions with which a machine should comply to be passed as safe. The investigation was conducted by officials of the London County Council and other bodies, who determined that all generators should come up to this standard: (1) The temperature in any part of the generator, when run at the maximum rate for which it is designed, for a prolonged period, should not exceed 130 degrees Centigrade. This may be ascertained by placing short lengths of wire, drawn from fusible metal, in those parts of the apparatus in which heat is liable to be generated. (2) The generator should have an efficiency of not less than 90 per cent, which, with carbide yielding 5 cubic feet per pound, would imply a yield of 4.5 cubic feet for each pound of carbide used. (3) The size of the pipes carrying the gas should be proportioned to the maximum rate of generation, so that undue back-pressure from throttling may not occur. (4) The carbide should be completely decomposed in the apparatus, so that lime-sludge discharged from the generator shall not be capable of generating more gas. (5) The pressure in any part of the apparatus, on the generator side of the holder, should not exceed that of 20 inches of water, and on the service side of same, or where no gas-holder is provided, should not exceed that of 5 inches of water. (6) The apparatus should give no tarry or other heavy condensation products from the decomposition of the carbide. (7) In the use of a generator, regard should be had to the danger of stoppage of passage of the gas and resulting increase of pressure which may arise from the freezing of the water. Where freezing may be anticipated, steps should be taken to prevent it. (8) The apparatus should be so constructed that no lime-sludge can gain access to any pipes intended for the passage of gas or circulation of water. (9) The use of glass gauges should be avoided as far as posssble, and, where absolutely necessary, they should be effectively protected against breakage. (10) The air-space in a generator before charging should be as small as possible. (11) The use of copper should be avoided in such parts of the apparatus as are liable to come in contact with acetylene. Adherence to these conditions, with those prescribed by the National Board of Fire-underwriters, is supposed to render the use of gasolene generators absolutely safe. — *Exchange.*

THE PARISH-PRIEST AND THE ARTIST. — A tragedy in the artwork of a painter recently befell a French artist, Henry de Groux, just as he was about to finish the interior of a chapel in a suburb of Paris. The chapel belongs to a monastic order, and his commission was no less than the decoration of the entire circuit of the walls. His subjects were the "Stations of the Cross," "Christ and the Scribes," the "Flight into Egypt," the "Crucifixion," and so on; and he worked hard for a year. Then he felt he must take a vacation for a few days. On his return something seemed to have happened to his mural work, the color-scheme was out, and several scenes had figures and buildings in them he had never dreamed of. At first he thought he was out of his mind, but a careful inspection proved that the trouble lay in the pictures and not his wits. He posted off to the priest of the parish, and got all the explanation he wanted. That worthy had found his pictures lacking in interest, in figures, in color, in snap. So he engaged a house painter and ordered him to put some pyramids in the "Flight into Egypt" for local color, and paint strong, bright gowns on the figures. In the scene on Calvary the burst of light had been painted black in order to give, as the parish-priest supposed, plenty of horror to the tragedy. In a few days he had ruined the work of a year through sheer ignorance and stupidity. — *N. Y. Times.*

NOTES AND CLIPPINGS. 40

THE Boston newspapers have joined in a chorus of laudation of the recent report of the Committee on School-houses, which strongly advises that the school-buildings erected for the city hereafter should be rigorously plain, outside and inside, using only the simplest materials, put together in the simplest way which will serve the purpose. It is true that the city of Boston needs a large number of new school-houses, and has only a small amount of money available for paying for them; and it is also true that certain school-houses have, in the past, been built and altered at an extravagant expense; but even these considerations do not quite reconcile us to the idea of building barns for young and impressible children to spend the most impressible years of their lives in. A great deal is said now about the extravagant cost of modern city school-houses, and the architects are indirectly blamed for this, as if it was to satisfy their tastes or whims that so much money was spent, but the fact is that nearly all the increased expense of modern school-houses over those of twenty years ago is incurred to carry out the rules of sanitation which are now enforced either by law or by an imperious public opinion. Where, a quarter of a century ago, a hole in the ceiling of a school-room to let the hot, and, presumably, foul air into the roof-space, with a couple of Emerson ventilators to discharge it thence into the atmosphere, were considered ample ventilation, the law of Massachusetts now demands that thirty cubic feet of fresh warm air per minute shall be supplied to every pupil in every public school building, and it is not the fault of the architects that, in order to meet this requirement, which is rigorously enforced by frequent inspections with anemometers and thermometers, steam-boilers, engines, fans, tempering coils, indirect stacks, valves and controlling devices of the most complicated and costly character are necessary, in place of the simple furnace, drawing its air-supply from the rooms, or, at least, from the hall, which sufficed two decades ago. The newspapers comment with wonder on the fact that the janitor service in the present Boston schools costs nearly ten times as much as it did twenty-five years ago; but where the janitor of 1875 simply put a few shovelfuls of coal on his furnace at night, and shook out the ashes in the morning, and swept the rooms once or twice a week, the modern janitor must either have passed an examination and obtained a certificate, as a competent steam-engineer, or must employ a licensed engineer to attend to the fans and engine, and a fireman to feed the boiler, while he makes his hourly rounds through all the rooms in the building, to assure himself that the thermometer in each is neither too high nor too low; that the inlet and outlet registers are open to the requisite extent; that the mixing-valves are working efficiently, and that inlets are so screened as to prevent undue draughts. If he neglects any of these duties, an unexpected visit of the inspectors may result in the loss of his position; and with these, the varying regulation of the water-supply to the plumbing-fixtures, which is now usually placed in the janitor's hands, and the necessary supervision of the sweeping and dusting of the building, the janitor of the modern school-house has his hands tolerably full, without being expected to use the coal-shovel, the oiler, the broom, or the dust-pan, himself.

WE should be very sorry to see any reduction made in these expenses. Large as is the sum paid out annually for the maintenance of our city school-houses, it is returned to the community tenfold in the improved health, both physical and moral, of the school-children of the present day over that of the children of the last generation; and an increased outlay, as, for instance, for baths in school-houses in poor districts, is, as the experience of Boston has shown, richly repaid. In the same way, we would like, notwithstanding the opinion of the Committee on School-houses, to see all new school-buildings designed with at least a little regard to the æsthetic advantage of those who are to occupy them. A little well-designed terra-cotta ornament about the entrance, or some good plaster decoration in the principal rooms, does not add much to the cost of a modern school-building, while the aggregate influence which they exert in arresting the attention of the thousands of children who see them every day, and in giving them perhaps the only glimpse of the higher life that some of them will ever know, is of incalculable value. To us there has always been something touching in the devotion with which the poor, overworked teachers in the public schools manage to find time to care for the plants and flowers which almost universally adorn the windows of class-rooms. It is evident that the teachers feel, perhaps almost unconsciously, the effect of these objects of natural beauty in softening the character of children, and, in relieving, for themselves as well as for their pupils, the depressing monotony of school duties; and the fact that the practice has become so widely spread among city school-teachers, who are often obliged to make a very appreciable sacrifice of their hard-earned money, as well as of time, to keep it up, shows how important they find its effect to be. It seems to us that this indication, like everything else in relation to school-houses which comes from the intelligent and observant persons who spend their lives in the effort to elevate the character of children, ought not to be neglected, and that the school authorities of Boston, who have provided a degree of security and healthfulness in their school-buildings unequalled, perhaps, anywhere else in the world, should recognize also the importance of developing the higher faculties of the young by the resources which only beauty, natural or artistic, can afford. A great deal has been done in Boston, as well as in other Massachusetts cities, by private generosity, in furnishing new school-houses with pictures, casts and other objects of art, to the very great advantage of the pupils. The public is ready to do much more in the same direction, and it is a pity to discourage it by a refusal to recognize art in the school-buildings. Nobody can put much enthusiasm into decorating a barn with statues, and even a modest sacrifice to art in the designing of new buildings, by encouraging people interested to do something to increase their artistic effect, would be well repaid.

THROUGH the generosity of Mr. and Mrs. Nelson Robinson, of New York, a travelling-fellowship in architecture has been established in Harvard University, of the value of one thousand dollars, to be awarded annually to graduates of the School of Architecture who have completed their course with distinction, or who have completed with distinction a post-graduate course of not less than one year. Selection is made from among the candidates by competitive examination, and candidates cease to be eligible on the completion of their twenty-sixth year. The winner of the award is required to spend a year in the study of architecture in Europe, under the direction of the authorities of the Department. The Austin Scholarship, maintained with substantially the same object for some years past, out of the income of the bequest of the late Edward Austin, has been modified, so that, instead of supporting a student in foreign travel, it is now to be devoted to the establishment of three ordinary scholarships in the Architectural Department, each with an income of three hundred dollars, for the assistance of undergraduates in the Department. It will be seen that, by limiting the eligible age to twenty-six years, rather younger material will be drawn upon for the Robinson scholarship than for most of the American travelling-scholarships, which set the limit of age, as a rule, at thirty years, following the limitation of the Paris School of Fine-Arts in relation to candidates for the Prize of Rome. Few men win the Prize of Rome before they have very nearly

Entered at the Post-Office at Boston as second-class matter

reached the age-limit, and American travelling-scholarships usually fall to men of a certain maturity, so that the result of sending out younger students from the Harvard School should be watched with interest. It has seemed to us for some years, judging by the designs shown at the annual exhibitions, that the work of the Harvard men often showed, at its best, a finer artistic sense than that exhibited by any other American school of architecture within our knowledge. It is very possible that this comes, at least in part, from the comparative freedom of the Harvard School from the rather overbearing Beaux-Arts influence which is sometimes found elsewhere; and it is also probable that the original material, selected from a community so old in culture and æsthetic sense as that which Harvard University represents is, taken as whole, of a finer fibre than that which is elsewhere drawn upon; but, however all this may be, the experiment of sending young men, whose individuality of talent has been guarded with special care, to study the masterpieces of architectural art at a particularly impressible age, is a most important one. Undoubtedly, many of the Robinson scholars will fall into the usual habits of ignorant criticism of everything that has not the stamp of French or Italian Renaissance, but there will certainly be some who, like the ablest of the French students, are capable of understanding the beauties of Amiens, or Chartres, or Arles, as well as those of the Louvre and the Farnese Palace; and it is on these that the hope of American architecture depends. We saw, not long ago, and, strangely enough, in a report of a lecture by an Englishman, the advice to young architects to begin their designs by considering what sentiment they wished to express in them. This was the first time, so far as we can remember, since the days of Garbutt, that we ever saw architects reminded, as a principle for practical application, that architecture is an art of expression. In the work of the Harvard School, we have seen, as we thought, indications that this principle was not forgotten there; and, if a curriculum which recognizes such a view of the art can be supplemented by an intelligent and well-directed study of the means of architectural expression employed by the greatest artists in the world, the influence of the new scholarship, both on the University and the community in general, will be very great.

PROFESSOR TROWBRIDGE, of the College of Architecture of Cornell University, has resigned his position, his resignation to take effect at the end of the academic year, when he will enter upon the active practice of his profession in New York. Professor Trowbridge came to this country with high honors from the Paris School of Fine-Arts, including the diploma of the French Government, which comparatively few architects, even in France, obtain; and it will be difficult to fill his place at Cornell. Meanwhile, his friends, and the whole profession, which has taken no small pride in his success, will wish him continued good fortune in his new field.

THE plans for remodelling the White House, at Washington, by adding curved wings and other features, seem, happily, to be laid at rest for the present, and some simple changes are to be made in the interior, so as to obtain more family rooms, while the President's business-offices are to be removed to a temporary structure, which will be built south of the White House, near the State Department. The cost of the changes will, it is estimated, not be more than one hundred and fifty thousand dollars, including such decoration as may be necessary, which, by the President's desire, is to be in the simple style prevailing in this country at the period of the original construction of the building. The whole scheme seems to be straightforward and practicable, and will commend itself to those who have been dreading for two or three years the consummation of the plan for making the White House ridiculous by appending to it the curved colonnades, with intercolumniations nearly equal to the height of the shafts, and entablatures held up by complicated framing, which, as the newspapers informed us, had been decided upon.

THE discussion over the competition for the Grant monument, in Washington, while it does no discredit to any one concerned, shows the difficulties which usually attend the proceedings of people who do not know their own mind, or are afraid to express a decided opinion. Without exception, so far as we know, the sculptors who have had anything to say on the subject have shown the utmost good feeling and sense of honor, and it seems to have been the Commission, which, by its hesitation in giving a frank and decisive award, has given good reason for complaint, not only to the two sculptors most interested, but to their fellows, who are earnest in their desire to see artistic competitions in this country put on a respectable basis, and are disappointed that this one, from which so much was expected, should have resulted only in a dubious award, which, like faint praise, is rather an injury than a benefit to the people on whom it is bestowed. The Commission say, in explanation, that, while the model of Mr. Shrady was "brilliant," they did not feel sure of his ability to execute a finished statue with the necessary "nobility and reserved power," and, at the same time, that Mr. Niehaus's work was of such a high order that they thought he ought to have another trial. All this is quite comprehensible, and, indeed, is rather creditable to the conscientiousness of the committee of award; but it may be observed that the terms of competition prepared by the Commission, and followed by the competitors, certainly implied that the models required would be sufficient to demonstrate to the jury the "nobility and reserved power" of the artist; or, at least, to give sufficient indication of the possession of these qualities by the artist to justify the Commission in making the award without reserve. If the Commission wished to be able to institute a subsequent test of "nobility and reserved power" between the competitors, it should have announced a double competition, in the usual form, one for sketches, and a second for large models; but, not having done so, it should have kept to its contract with scrupulous fidelity. We do not fear, as some of the sculptors do, that the disappointments connected with this competition will prevent the submission of similar competitions in future to expert juries; but we regret to see a young and talented sculptor deprived of a portion of the credit which he has fairly won, by the apparent reluctance of the jury to believe in their own award, and we regret equally that Mr. Niehaus, a man whose talent and character are honored throughout the country, should have been placed, entirely against his will, in the position of one endeavoring, or even consenting, to subtract, for his own benefit, from the credit of a preferred competitor.

THE Twenty-sixth Annual Report of the Trustees of the Boston Museum of Fine-Arts is a particularly interesting one. In the first place, the Report gives assurance of the completion of the purchase, by the Museum, of its splendid lot on the Fenway, containing nearly twelve acres of land, surrounded on all sides by parks or streets, none of which is less than eighty feet wide between the building-lines. As it is generally understood that the Museum has sold the lot which it now occupies for nearly two and one-half million dollars, it seems to be sure of suitable accommodations for the future. It ought, however, to be remembered that two millions and a half is by no means an inexhaustible sum for a public building intended for the fine-arts. The Trustees have been wise enough to secure a tract of ground large enough for their needs for many years to come; but the payment for this tract will absorb a considerable portion of the price of the old lot; and, with what remains, it will be possible to complete a building which will contain the present collections, but without much room to spare; and, for future enlargements of the collections, additional buildings will undoubtedly be necessary. Meanwhile, the collections belonging to the Museum seem to be growing at a rate which is surprising, in view of the great and constantly increasing difficulty of obtaining genuine antiquities, or works of art by noted masters. Within the past eight years, the Museum has expended, out of its own funds, more than six hundred thousand dollars in purchasing objects of art which, in all probability, could never have been secured later; and its acquisitions from donations and bequests, although not so easily measured in money value, are probably not less important. It is gratifying to note an apparent increase in the popular favor with which the Museum is regarded, as shown both in the number of paid admissions, and in the amount of donations and subscriptions. The total number of admissions in 1901 fell a little short of that of 1900, owing, undoubtedly, to the progressive transformation of the portion of the city in which the Museum is situated from a residential to a business quarter. With the removal of the Museum to the Fenway, five or six years hence, the number of free admissions is likely to diminish, as the Fenway is, as yet, rather removed from the range of sightseers; but it is almost in the centre of the residential portion of the Metropolitan district, and should attract a much larger number than ever of serious students, who will find the conditions of work in the quiet grounds fronting the Park far more agreeable than in the noisy and crowded Copley Square, with its streams of electric-cars, its hotels, railroad-stations, concert-rooms and shops.

THE AMERICAN VIGNOLA.[1] — VII.

PART I. — THE FIVE ORDERS.

DRAWING.

GENERAL Proportions. — Since the relative size of all the parts, in Vignola's Orders, is fixed, any of them can be drawn out in accordance with these rules, if a single dimension is determined. The width of a Dentil or the length of a Modillion suffices to determine everything else. But the data generally given are either the lower Diameter of a Column, the height of a Column, or the whole height of the Order, with or without a Pedestal.

I. If the lower Diameter is given, the procedure is as follows (90): Divide it in two, draw the axis of the Column, and then divide each half into three equal parts. This gives the scale of sixths. Divide in two the two outer sixths. This gives the upper Diameter of the shaft, which is five-sixths. Lay off upon the axis the height of the Column, by Diameters (7, 8, 9 or 10), and of the Entablature, which is one-fourth the height of the Column. Mark the height of the Base, half a Diameter, or three-sixths, and then that of the Capital, two, three or seven sixths. Divide the total height of the Entablature into 7, 8, 18 or 10 equal parts, according as it is Tuscan, Doric, Ionic or Corinthian, or use halves, quarters or eighths of a Diameter.

Mark, then, the heights of the Architrave, Frieze and Cornice, drawing horizontal lines through the points of division. Then carry up vertically the outer lines of both the upper and the lower Diameters of the Shaft, drawing from the point where the line of the upper Diameter cuts the lower edge of the Cornice a line at 45 degrees to determine the projection of the Cymatium, or that of the Mutule or of the Corona.

Add one-third the height of the Column for the Pedestal. Divide this into three equal parts, taking the upper third of the upper third for the Cap, and the lower two-thirds of the lower third for the Base. Vignola makes the Base of the Pedestal only one-ninth of the height of the Pedestal instead of two-ninths, as here determined. (Figure 90 illustrates this procedure for the Tuscan Order.)

II. If the height of the Column is given, a fourth part of this added at the top gives the height of the Entablature, and a third part added below gives the height of the Pedestal. One seventh, eighth, ninth or tenth of the height of the Column gives the lower diameter of the Shaft (90). The drawing may then be carried forward as above.

III. If the total height of the Order is given, without the Pedestal, a division into five equal parts gives four parts for the Column and one for the Entablature (90).

If there is a Pedestal, and it is of the regular height of one-third the height of the Column, the division of the total height must be into nineteen equal parts, four of which go to the Pedestal, twelve to the Column, and three to the Entablature (91).

The lower Diameter can then be obtained from the height of the Column, and the drawing completed, as above.

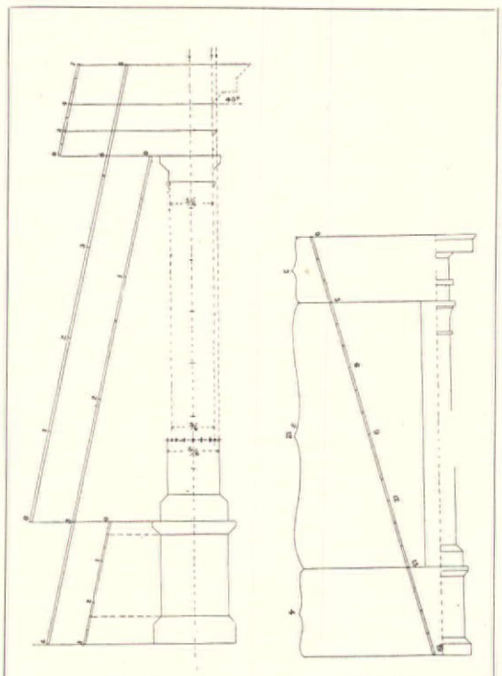

Fig. 90. Fig. 91.

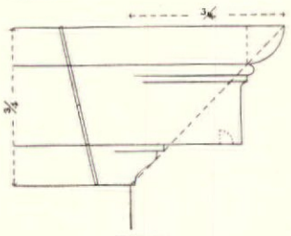

Fig. 92.

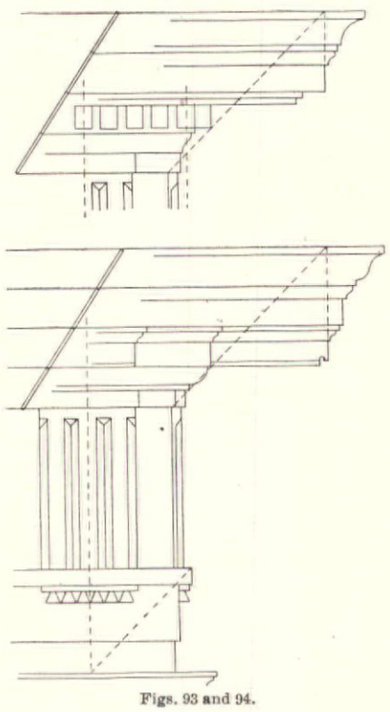


Figs. 93 and 94.

Note. — The division of a given dimension into equal parts may be effected with the dividers, or, more easily, by using a scale of equal parts which are the same in number as the desired subdivisions, but a little larger, and holding this scale obliquely between the extreme limits of the space to be divided (90, 91).

The division of vertical dimensions into five, seven, eight, nine, ten, eighteen or nineteen equal parts, as here required, is thus easily accomplished. To ensure accuracy, the lines marking these divisions should be horizontal, not normal to the direction of the scale.

Cornices. — The Tuscan Cornice may be drawn by dividing its height into quarters, as is done in the figure, giving the upper quarter to the Ovolo and the lower to the Bed-mould, and giving the middle half to the Corona, Bead, and Fillet (92). A 45-degree line gives the projection of the Bed-mould, Ovolo, and the Cornice itself.

The Doric Cornice is also divided in four equal parts, the upper one comprising the Cymatium and Fillet, the next the Corona and the small Cyma Reversa above it, the third the Mutules, or the Dentils with the Mutules above them, and the lower one the Bed-mould, including the Cap of the Triglyph, which is narrower in the Mutulary Doric than in the Denticulated, by the width of the Fillet above it (93, 94).

A 45-degree line drawn outward from the middle of the top of the Abacus gives, where it cuts the lower line of the Frieze, the projection of the Tænia. A similar line, where it cuts the upper line of the Frieze, gives the axis of the next Triglyph (84). The Triglyphs are drawn next, with their Cap, and the Regula

[1] Continued from No. 1359, page 12.

and Guttæ, then the Mutules, or the Dentils.

In the Doric Order a line at 45 degrees drawn from the bottom of the Cornice gives the face of the Corona in the Denticulated Doric, the face of the Mutule in the Mutulary; in the other Orders, a similar line gives the projection of the Cymatium (93, 94).

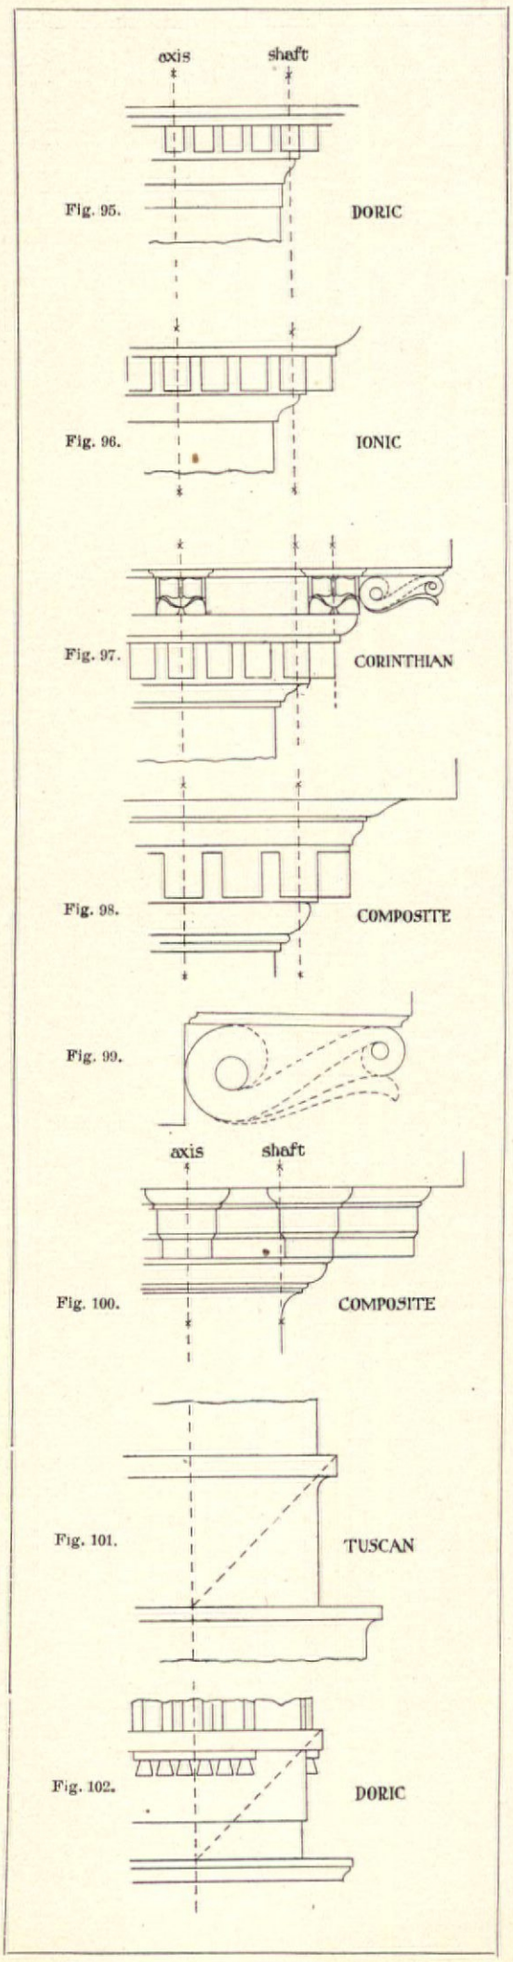
In putting in Dentils, draw first the one over the Axis of the Column, then the Double Dentil, the first half of which is centred over the lower face of the Column, and then the intermediate ones, three, two, or one, according as the Order is Doric, Ionic or Corinthian, or Composite (95, 96, 97, 98). The Interdentil is half the width to the Dentil, except in the Composite.

One Corinthian Modillion comes over the axis of the corner column, and one over the outer face of the Double Dentil (97). In drawing the side of a Modillion, put in first, at the outer end, a semi-circle half its height and one at the inner end nearly the whole height; then the rosettes, one twice as large as the other; then the connecting curves, and finally the leaf beneath (99).

In Palladio's Composite Cornice, one block is set over the axis of the column, and the double block at the corner has its inner face on a line with the face of the Frieze below. The blocks are about half a Diameter o. c., the inter-block being one-twenty-fourth of a Diameter wider than the block itself (100).

Architraves. — The Tuscan Architrave (101) has but one fascia, or band, the Composite two (105), and the Corinthian three (104). The Doric has sometimes one, but generally two (102), and the Ionic has generally two, but sometimes three (103). The lower band is always the narrowest and is set on a line with the face of the Shaft below and of the Frieze above.

All the Architraves have a Cymatium, or crowning member, which in the Tuscan and Doric is a broad Fillet called the Tænia, and in the Ionic and Corinthian is a large Cyma Reversa, surmounted by a Fillet and generally supported by a bead. The lower bands often have, as a Cymatium, a small Cyma Reversa, Bead, or Ovolo, and all three bands are sometimes sloped backward, as in the Entablature of the Palazzo Vendramin-Calergi, at Venice (106), so as to diminish the projection of the crowning mouldings, which generally have a projection, beyond the face of the Frieze, equal to their height.



The Tuscan Tænia has beneath it the characteristic Tuscan congé (101). Beneath the Doric Tænia, and directly under each Triglyph, (102), is a narrow Fillet, which sometimes has a bevelled face, called the Regula, beneath which are the six Guttæ. These are sometimes frustra of cones, as in the Greek Order, sometimes of pyramids. The Guttæ, which almost touch at the bottom, are twice as high as the Regula. Both together are just as high as the Tænia, or one-twelfth of Diameter, so that the three are one-sixth of a Diameter high. They accordingly occupy the upper third of the height of the Architrave, which is three-sixths high, the lower band occupying the lower third.

The two lower bands of the Corinthian Architrave occupy half its height, and the lower band with its Cymatium is just as wide as the mouldings that crown the upper band. The second band with its Cymatium is just as wide as the third band without (104).

Capitals and Bases. — In drawing Capitals, it is best to put in first the axis of the column and the vertical faces of the Shaft; then the horizontal lines, and lastly the profile, beginning at the top. But in drawing Bases it is best to put in the profile of the moulding before the horizontal lines.

The Tuscan Base (107) is half a Diameter high, half of which goes to the Plinth and half to the Base Moulding, which is made to include the Cincture, or broad Fillet at the bottom of the Shaft, which in the other Orders is not counted as part of the Base. But this is merely saying that the Tuscan Base is not quite half a Diameter high.

All the other Bases, including the Attic Base, are just half a Diameter high. All the Plinths are eight-sixths wide and one-sixth high, except the Tuscan and Doric, which are one-quarter of a Diameter high. It is not worth while to define the proportions of the other Bases.

The Tuscan Capital (107) is half a Diameter high, or three-sixths, the upper sixth comprising the Abacus with its Fillet, the middle sixth the Echinus and the Fillet below it, and the lower sixth the Necking. The upper Fillet is a quarter of a sixth wide, the lower one a sixth of a sixth.

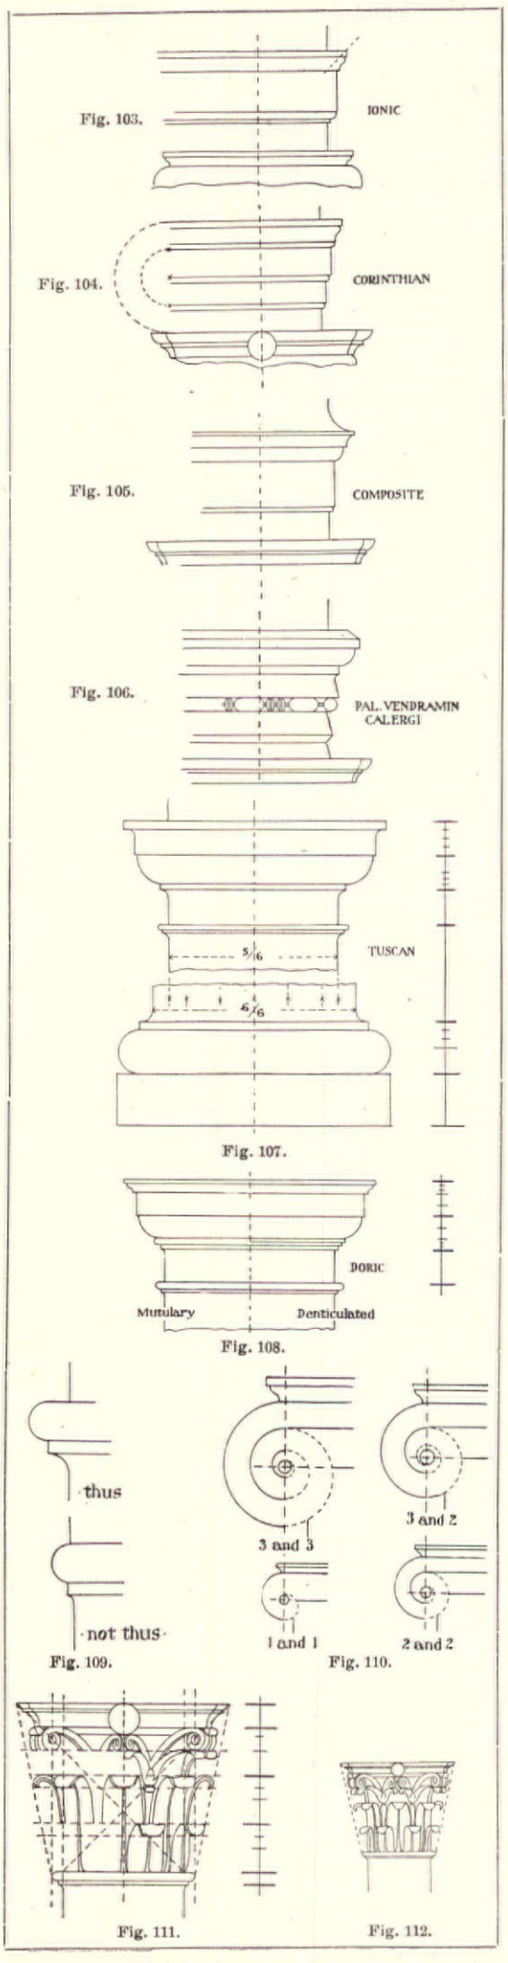
The Doric Capital (108) is also three-sixths of a Diameter high, the two upper sixths being divided into thirds, and these again into thirds, to give the height of the smaller mouldings. The Denticulated Capital generally has three Fillets, the Mutulary, a Bead and Fillet.

The Astragal, which in the other Capitals is $\frac{1}{12}$ D. high, or half a sixth, is in the Tuscan and Doric Orders one-fourth smaller, or $\frac{1}{16}$ D., the Bead being $\frac{1}{24}$ D. high, or a quarter of a sixth. In drawing the Astragals, draw first the horizontal line at the top, which occupies two-thirds of the projection, otherwise the Congé below is apt to be slighted. The Bead and Congé should have their full measure of 180 degrees and 90 degrees (109).

The Ionic Capital, which is one-third of a Diameter in height, or four-twelfths, is also divided into three parts, but unequally. The Abacus occupies the upper twelfth, or one-quarter, and had better be put in first. The Echinus occupies rather more than half of the remaining space, namely five-ninths. In the Composite Capital, the Abacus occupies the upper sixth, and a little more, and the Echinus and the Astragal the next one (98).

The Eyes of the Ionic Scroll come in line with the top of the Astragal and with the lower Diameter of the Column, and should be put in first (110). The Scrolls make three complete turns and finally are tangent to the upper side of the eye. They can best be drawn by putting in first three semicircles on the outer side, and then three smaller ones on the inner side. In working on a small scale, two semicircles on each side suffice, or three on the outer side and two on the inner, as in the plates. But one is never enough (110). The Eyes of the Composite and of the Roman Ionic Capitals are set nearer together.

In drawing a Corinthian Capital (111), it is best to put in first the Astragal and the lower line of the Architrave, carrying up on each side the outer lines of the shaft; then the Abacus, Fleuron and Scrolls. The double scroll at the corner falls just outside these vertical lines. It is slightly elliptical in shape, not circular, and the outer scroll is more elliptical than the inner, being more foreshortened. The small scrolls under the Fleuron are also foreshortened into ellipses. Then the five leaves of second row,



the middle one in elevation, the two side ones in profile, and the other two at 45 degrees, carrying down the mid-ribs to the Astragal. Their tips turn down half a sixth, those of the corner leaves coming just on the outer lines of the upper shaft. Of the four leaves of the lower row, the two inner ones occupy the spaces between these mid-ribs, and the ends that turn over fall entirely within the outline of the lower parts. The two outer leaves extend on either side slightly beyond the width of the shaft below, and their tips fall just outside the lower line of the leaves, being about six-sixths of a Diameter apart. They accordingly come just over the outer lines of the lower Diameter, just as the tips of the corner leaves above them come on the lines of the upper Diameter.

A line drawn tangent to the Astragal and to the Abacus is also tangent in all three rows of leaves, very nearly. The Caulicoli, the Buttons, the third row of leaves, and the lower parts of the Volutes follow, in this order.

The smaller the scale of the drawing, the more straight and upright should the Acanthus leaves be made (112).

W. R. WARE.

[To be continued.]

SOME REMODELLED COLONIAL CHURCHES.

THROUGHOUT that portion of the United States lying east of the Alleghanies, there are a large number of church edifices built during the eighteenth and the early years of the nineteenth centuries, which are still used by religious bodies as houses of worship. A few are of stone, more of brick, but the majority are of wood. Nearly all of them are to be found in that portion of the country comprised by the original thirteen States, and of these, by far the greater number are in New England.

The reason for this distribution is simple. In Massachusetts, there were in 1800, seventy-five inhabitants to the square mile; in Virginia, there were only nine to the square mile. There were not over a half-dozen towns in Virginia with a population of over a thousand. There were forty in Massachusetts.

The prevailing Protestant creeds in New England at that time were Congregational, Baptist and Methodist, all of which leaned rather to segregation of church bodies than to consolidation. The tendency of the leading denominations south of New England, Presbyterian and Episcopalian, ran toward consolidation, so that outside of New England, even in the States with greater

population, the churches were fewer, though often larger and more elaborate.

We are apt to think of the older Southern cities as having to-day more examples of "Colonial" architecture than the Northern, but there are more churches standing in Boston which were there in 1810 than there are in Charleston, S. C., just as there are more old buildings of all descriptions.

In 1810, Charleston had seventeen churches to Boston's twenty-one, and a population of 24,500 to Boston's 33,000. But Boston's proportionately greater increase in population has hidden the older work from sight.

There are few towns of less than 50,000 people in any of the New England States which do not have at least one or more of the typical "old white meeting-houses." Many of them are not a century old, but nearly all, if not all, are of the type broadly classed as the Colonial, and nearly all of wood. In plan, they resemble very closely the more elaborate buildings of stone or brick, of which a few examples are left in the larger cities.

They are pretty thoroughly built as to frame; some of them have held their clapboards and shingles for three-quarters of a century. A few in their detail are elaborate, and generally the detail is good, even in buildings where there is but little.

The preponderance of these wooden churches over those of brick and stone is due mainly to the fact that the congregations of the smaller towns and cities where they were built have not grown as rapidly as in the larger cities. The building of seventy-five or a hundred years ago is still ample for the church society. It is doubtless true, too, that, in proportion to population, there is — or was — a more intense interest in religion in the smaller communities. In 1837, for example, Boston had one church to 1,230 of her population; the town of Bolton, in the same State, had a church to every 280 of her population. It is not surprising, therefore, that the Bolton churches are of wood, nor surprising to find, even though the Bolton ratio may be an extreme one, that the wooden churches outnumber the brick and stone.

Out of this multitude of frame churches, that are still standing, and that are used by religious bodies, there are many which are practically unchanged, save for a few coats of paint, a little more genial atmosphere induced by modern heating methods and modern theology, and a new shingle or clapboard here and there. Others have been transformed externally by Gothic spires and turrets, and "art glass" windows, but remain, as to framework and plan, the same. And it is with the enlargement and renovation of a few of these older churches that this article has to deal.

In the following examples, an endeavor has been made to preserve in the appearance of the buildings as much as possible of the Puritanized Renaissance style, which is the main characteristic of our earlier church-architecture, and, at the same time, provide for the demand, in one instance, for an increased congregation; in the others, for changed methods of church-administration.

It may be noted in passing that all these churches are Congregational, and therefore of the type which, rightly or wrongly, represents in New England the Puritan and Pilgrim spirit.

. . . . . .

Although this article refers to the region east of the Alleghanies as that portion of the country which would be considered, the first of the buildings chosen lies west of the Alleghanies.

Marietta, the oldest city in Ohio, was founded by a body of emigrants from Massachusetts and Connecticut who, under the name of the Ohio Company, and led by General Rufus Putnam, of Connecticut, travelled overland to Pittsburgh, and then by water to the site of the present city. In 1806, eighteen years after the settlement of the town, the Congregational Church, the oldest of the three buildings chosen, was built. Up to 1900, the only change in the building was an addition at the rear to hold the organ, and the cutting off of a portion of the church to form the front vestibule, the original vestibule having been a one-story lean-to, between the towers on the front of the church.

It was the idea of the church society to preserve as much as possible of the old building. The frame was practically sound. The instructions to the architects were to double the seating capacity of the church, make the galleries available, improve, if possible, the exterior appearance of the building, and not spend over $15,000 in the process. The two plans show the relative size of the building before and after alterations. The gallery was dropped about two feet, and the pitch of the gallery floor increased, and by carrying it across the ends of the transepts, it was possible to reach it by staircases from either side of the pulpit platform. At the front of the church, the floor of the old portion was given a slight pitch, but the floor of the new part kept level. On either side of the organ space, there are dressing-rooms and choir-room, and a pastor's room, reached from the main floor of the church and from the landings of the galleries. The old interior finish of the church, which was simple but good, was retained, and the new, so far as possible, is like it.

The exterior of the original church is particularly striking in its two towers. So far as I know, it is the only so-called Colonial church in America which has them.

It has been suggested that French or Spanish influence may have entered into this. It is known that quite a large number of French emigrants settled here in the early years, and there was, of course, some Spanish intercourse from St. Louis by the way of the Ohio River.

It seems more probable, however, that the façade of St. Paul's, in London, may have been in the minds of the builders, or that the two towers are due to the desire to surpass the buildings which the new colonists had left in New England. So far as design and proportion went, the towers were exceedingly bad, and, in fact, the exterior is not nearly so good as the interior, either in its general design or its detail. The door and the window casings of the interior are refined, and evidently studied with a good deal of care, but those on the exterior are crude. It is very surprising, however, that so much detail is present at all when one considers that less than twenty years before the church was built, the nearest town lay several weeks' journey away, through an unbroken wilderness. Marietta was more isolated in 1806 than the smaller towns in New England of 1680.

The second example, the church at Ware, Mass., is changed but very little, so far as the exterior is concerned, the only changes on the front (which is the main architectural feature of the church, as of most Colonial churches) being an elaboration of detail. Instead, the essentials called for were three: More Sunday-school room, more choir and organ space, and a gallery which not only could, but would, be used. These additions have been satisfatorily made from a practical point-of-view. It is a question whether the interior of the church before alteration was not quite as pleasing as it is to-day.

The church at Williamsburg, in Massachusetts, belongs to a later type of architecture, that of the Greek revival, but it was so poverty-stricken in its carrying out that it seemed hardly necessary to keep closely to the original type. The extra room called for here was needed in the form of two parlors and a larger Sunday-school room, and the limitations of the site left only the front of the church available for an addition, as the rear of the church came close to a steep ledge at the foot of the hill. The fact that these smaller rooms necessitated numerous windows influenced the decision as to the style of architecture, for it seemed that the older Colonial work, with its lighter detail, would harmonize better than the later type of the original church.

In all three of these examples the problem has been to reconcile three factors: Sentiment, economy and practical necessity. They don't harmonize perfectly, perhaps, but the attempt has at least been interesting to those who made it. G. C. G.

STRUCTURAL COLOR-DECORATION OF THE INTERIOR OF PUBLIC BUILDINGS.[1] — II.

BEFORE speaking of different forms of painting available, I would like briefly to touch upon the possibilities offered to us by the use of marble, mosaic and plaster, *stucco duro* and sgraffito. These are so closely allied to the first division of the subject, that I would speak of them here. We know that the Egyptians, Greeks, and Romans used color largely in their buildings, but we can have but little idea of the magnificent effects often attained by means of their fresco-painting, encaustic-painting, *tempera*, modelled plaster, mosaic, marble linings and veneering, bronze, ivory, gold and silver overlaying, and inlaying.

For instance, we read of the Golden House of Nero, that the walls were encrusted with gems and mother-of-pearl; of banqueting-halls having ivory ceilings; of a ceiling in the State dining-room, which was spherical in shape, and cut in ivory to represent the constellated skies, and kept in constant motion by machinery in imitation of the stars and planets. This magnificence, inventive and symbolic, partook something of the marvellous and the rare, qualities which we have far to seek in this prosaic age. In their large halls, basilicas, and baths, it was also a custom of the Romans to line the walls with marble slabs to a considerable height, and above to use mosaic or plaster reliefs. The vaulted ceilings were generally coffered, and decorated in plaster reliefs, colored and gilt; bronze rosettes were also used in the coffers.

These were general forms of decoration throughout the Roman Empire both in the West and East. We find them used by the Byzantine builders, in Constantinople, Sicily and Italy, and we may be of opinion that few finer schemes of decoration have ever been devised. In some manner adapted to our modern needs they are available to-day, and it is understood that marble and mosaic are to be adopted in the new Roman Catholic Cathedral at Westminster.

In considering the use of mosaic at the present time, we may hope that the modern and vicious habit of preparing mosaic tesseræ face downwards on a sheet of paper laid on a flat table, and then pressing the sheet of paper into position on the wall, has been finally given up. The old and only right method is to fix each tessera into the cement pushed in by hand from the front. Too many works of the last century are deficient in one of the most important elements of decoration, namely, the right technique. Sir William Richmond, in St. Paul's Cathedral, the largest example of mosaicwork of modern times, has shown in the work which he has done there that there is no more trouble and no appreciable loss of time in doing mosaic-work in the only true way, viz, pushing it in, tessera by tessera, from the front. His assistants after very little practice have been able to do the work on these lines with the greatest rapidity, and naturally with intelligence and interest in seeing their work in position as it proceeds.

Time will not permit me to speak of modelled plaster and sgraffito in any detail, except to express the satisfaction we must all feel that these ancient arts of tried quality are understood and worked in a

[1] A paper by Gerald C. Horsley read before the Society of Arts, and published in the *Journal* of the Society. Continued from No. 1374, page 32.

modern spirit to-day. The composition of *stucco duro* has been often described, and we know by the remains of ancient Roman work found in the Villa Farnesina, and of the works of the sixteenth century in the Loggia of the Vatican, and the Villa Madama, and other buildings in Italy and France, what exquisite possibilities this material presents. The work, particularly in the early Renaissance, was usually decorated in color. This was generally laid on while the stucco was wet as in fresco, and the details heightened with *tempera* or encaustic colors, and accessories enriched in gilt *gesso*.

We may congratulate ourselves that artists like Mr. George Frampton, A. R. A., and Mr. Anning Bell have worked in this material in churches and other buildings in our time. The processes of *stucco duro* and sgraffito are fully described in the "*Arts and Crafts Essays*" published in 1893, the former by the late Mr. G. T. Robinson, and the latter by Mr. Heywood Sumner, whose work in All Saints' Church, Ennismore Gardens, affords an example of modern treatment. I need not do more than name these two forms of lasting decoration, peculiarly structural, and available to us to-day.

I may be blamed for not referring with greater fulness to the painted wall-surfaces and roofs, of which there are many, in our modern churches. This work is raising itself above mere commercial expression, and under the direction, and with the coöperation of the architects of these buildings, we have instances by many painters of ability and knowledge.

If there is one thing which may strike us in this modern work as being different and inferior to the best work of the old time, it is a very general want of use of the full brush of color carried through the work with bold and masterly sweep, avoiding thereby, in the necessary repetition of a pattern, the mechanical and accurate repeat so constantly seen in modern work, and never to be found in the old.

What makes so much ecclesiastical decoration of the present day so devoid of interest is just this absence of intelligent handling. We are better without color if it is not used in a manner consonant with its dignity. We may be sure its revenge on us will be ample if we use it in any other way, as much in the lowliest border or diaper as in the picture it may surround.

In our theatres and places of public entertainment, the same progress is, alas, not being made. The desire of the modern theatre-manager to build a theatre, and to open it in six months, is against the production of anything else than a place in which plays may be produced. We are far behind the French in this matter. In Paris the foyers and staircases of the principal theatres are notably decorated by artists; so that the audience has the privilege of knowing that it is not in a mere box of upholstery, but in a temple devoted to the arts. I am inclined to think that were our theatres of the latter kind the interest of the audience in the art of the drama would be quickened and encouraged.

And now as to the principal methods in use by painters at the present time. Probably, the world has never seen a more beautiful method of painting than buon or true fresco, but, alas, its use has not been fully justified in this country. The Royal Commission I have just referred to took a good deal of evidence as to its suitability for the decoration of the Houses of Parliament. A number of painters of eminence spoke against its being attempted. They advocated the use of oil-color. But the Commissioners, perhaps dazzled by what were then considered the triumphs of modern art, — the frescos at Munich, decided that the new paintings should be in that method.

Dyce, Cope, my father, and one or two others were successively commissioned. Exposed, however, to the bad air of their surroundings these works have, in some cases, suffered beyond repair. So doubtful were the painters themselves as to the suitability of the scheme, that when Maclise was commissioned to paint the walls of the Painted Chamber he, with the sanction of the Commissioners, proceeded to Germany in order to make researches into the practice of stereochrome, or water-glass painting. The result was that he adopted the process in the large wall-painting, "The Meeting of Wellington and Blucher after the Battle of Waterloo"; it was also adopted by Mr. Herbert, who was then engaged on other wall-surfaces in the palace.

You will permit me to remind you of what happens in buon fresco. The powder-colors mixed with lime-water are applied to the last and freshly-spread coat of plaster before it has had time to absorb more than a trace of carbonic-acid from the air. The painting-ground is, in fact, saturated with an aqueous solution of hydrate-of-lime, that is, slaked lime, while there remains a large reserve of this compound in an undissolved condition. When on such a surface a layer of pigment mixed with water is placed, as that water evaporates the lime-water in the ground diffuses into the paint, soaks it through and through, and gradually takes up carbonic-acid from the air, thus producing carbonate-of-lime, which is the actual binding material.[1] The whole painting gains in this chemical action, appearing to absorb light and to reflect it from the sand facets of the ground to the spectator.

But, unfortunately, and here I again quote from Professor Church's interesting book "*The Chemistry of Paints and Painting*," "the protection afforded to the pigments by the binding material, this carbonate-of-lime, is not generally very efficient. In the case of a dry wall, free from soluble saline matter, and exposed to a pure atmosphere, it may remain good for centuries. But in air contaminated with the products of the combustion of coal and gas, and with tarry and sooty impurities, a fresco picture soon perishes. The binding carbonate-of-lime is converted into the sulphate, breaking up the paint. The same causes will form sulphate-of-magnesia from the carbonate-of-magnesia in the plaster, and the paint will scale off."

In our large towns, therefore, to-day, buon fresco has no chance of lasting.

The stereochrome, or water-glass, process consists in spraying the painting after completion with a warm dilute solution of potash-silicate, or potash-soda silicate, which is obtained by fusing the purest sand obtainable with carbonate-of-potash or carbonate-of-soda. The pigments themselves are mixed with some of the fixing liquid. This form of painting is a German invention of comparatively recent date; it has not been frequently used in this country, and we have very little experience of its behavior.

In the consideration of the possibilities of *tempera* painting we find ourselves on surer ground, no longer so fearful of the consequences of the contaminated atmosphere of our towns. I am glad to be able to read you a few words I have received from Sir William Richmond as to this medium, which he used on the walls of a modern church at Cheltenham a few years ago. He says: —

"The wall was prepared with lime and sand, the final *intonaco* was in marble-dust and well-slaked lime, and it was wonderfully white. The whole design was drawn in charcoal, corrected with care. Egg, Capri wine and powder-colors were used. The yolk of egg alone was used, plenty of wine and distilled water. The first painting should be in what the Italians called 'Verdaccio,' namely, raw siena (black and white), with plenty of *impasto*. In two hours this can be glazed with warm color and painted into. I am quite certain that the yolk of egg and wine form the very best and most durable medium for wall-painting. Most of the Italian wall-paintings which have lasted were not painted in fresco, but in the *tempera* of yolk of egg, the essential oil of which is a most powerful binding liquid, enabling the painting to dry like a rock."

Sir William further says: —

"I prefer yolk of egg and wine, even to buon fresco; the color is almost as pure, not quite so light, and if it is necessary to get rich color, the medium will give it to any extent."

Professor Church, speaking of the large amount of oil in the egg-yolk says, "This vehicle does not act so effectually as oil and varnish in locking up pigments, and so the protection against change which it affords is less." But I think we may take it that the protection is certainly considerable, while the old method of varnishing the painting with sandarac in oil affords further protection against moisture and impure air.

The well-known spirit fresco, invented by the late Mr. Gambier Parry, differs little from ordinary oil-painting on account of the large quantity of oil in the copal, which forms so much of the medium, the constituent parts of which, I may remind you, are only multiples of these proportions, viz.: —

	ozs.
Gum elemi or elemi resin	2
Pure white wax (beeswax)	4
Oil of spike lavender	8
Finest preparation of artists' copal	20

With this medium incorporated by heat all colors in dry powder are mixed. It appears that Mr. Gambier Parry gave the name of spirit-fresco to the method because oil of spike and turpentine may be freely used as liquids during the process of painting. The beeswax secures, of course, a perfectly matt, or dead surface, but it is liable to produce a kind of bloom in the course of years, and may wholly disappear in the course of time.

Besides the paintings by Mr. Gambier Parry at Higham and Gloucester Cathedral, Lord Leighton's "Arts of War" and "Arts of Peace," at South Kensington, and seven paintings by Ford Madox Brown, in the Town-hall of Manchester, are examples of this method. They appear to be standing well, though we may expect them to darken, and there are a few signs of the bloom referred to above in the "Arts of Peace."

Professor Church considers that a sound medium is to be found in the proportions of: —

	ozs.
Oil of spike	12
Paraffin wax	4
(The two mixed by heat.)	
Copal picture varnish	20

He advises the pigments being mixed in blown linseed-oil, rather than in the medium itself, as Parry recommends.

I need not do more than allude to Parry's Ely medium. Briefly it is: One part pale drying oil; one part strong copal varnish; two parts japanner's gold-size; two parts turpentine, and the powder-colors to be ground up in the medium. It is just oil-painting over again with the gold-size to give the necessary deadness of surface. He painted the eastern part of the nave, wooden roof, also the octagon and transept ceiling at Ely Cathedral in this medium.

I have dwelt on the component parts of these wax and oil mediums in some detail, as it is but a step from them to the method which is generally adopted by painters to-day. I refer to the prevalent custom of painting in oil on canvas, and then, on completion of the picture, having it fixed, or *marouflé*, as the French call it, to the wall or ceiling; that is to say, the canvas is fixed by means of a thick paste of white-lead, oil and copal varnish spread upon the wall and simultaneously upon the back of the canvas.

[1] I am indebted to Professor Church's "*The Chemistry of Paints and Painting*" for this description.

The French painters in the beginning of the nineteenth century, like their German brethren in Munich, painted mural works in fresco, but they were already beginning to discard the practice when we in our wisdom were working in it at Westminster. They also used encaustic-painting (Delaroche's "Hemicycle" in the École des Beaux-Arts is an example), but since 1870 the most important works have been painted on canvas fixed in the way I have described; such are the great wall-paintings by Puvis de Chavannes, in the Panthéon, in the museums of Amiens, Rouen and Lyons; the Sorbonne, and the Library in Boston.

This, too, is the method adopted in the Royal Exchange, at Liverpool, at Glasgow, and by Messrs. J. S. Sargent, R. A., and E. A. Abbey, R. A., in the Library at Boston.

Without going deeply into technicalities which would naturally vary with each painter, the colors used are simply oil-colors, with a medium of wax and turpentine. Professor Moira, who has painted in this way at the New Renshaw-Street Chapel in Liverpool, and at other places, tells me he likes the canvas to be fairly coarse and open, so that there should be no hindrance to the fixing material incorporating itself with the colors laid on. This is better achieved by doing the first painting only in the studio, and completing it *in situ* after it has been fixed upon the wall or ceiling. The painting of the picture *in situ* in this way will, I am sure, commend itself to all as a most important side of this system of decoration. It is understood that some of the modern works I have named have been painted entirely in the studio; corrected in many cases, no doubt, when in position. But as a practice it must surely carry with it its own condemnation. Although scale-drawings and models may be made with the utmost care, and cartoons in full size tried in position, all of which should be done, and invariably are done, before the painting is begun, unless the work, or at least the major part, is carried out in the building, it is not possible for the painter to be confident as to the correctness of his scale, or, what is more important in its difficulty, of his color. Both these elements, more particularly the last, must surely be influenced by the size and lighting of the building, an intimate knowledge of which is revealed by working in it. Are we to suppose that the ceiling of the Sistine Chapel would have been as magnificent as it is if it had been painted by Michael Angelo in a studio and then fixed in position? I confess the very thought is sacreligious, and I tremble at suggesting it.

In this connection, I am reminded of a painting on canvas, in St. Alban's, Holborn, which was painted chiefly on the wall, where, by its position in a dark corner of a church, certain colors had to be used which are startling in what would be their inappropriateness in a better light. For instance, in order that the hair of the Saviour, one of the figures in the composition, should appear brown, pure vermilion had to be largely used; ordinary light brown appeared black.

But it is unnecessary to multiply instances, and I would venture, therefore, only to suggest that, as, in most cases, the position of the painting directs the color to be used, it is desirable that it should be, as far as possible, painted *in situ*.

It is to be hoped that the convenience of this modern method of painting on canvas will not deter painters from working directly on the plastered wall in *tempera*, oil, or encaustic. If the beautiful qualities of fresco are denied to this country, there are yet the qualities inseparable from a plaster ground, which a canvas surface can never present in the same way.

Design I need not touch upon. There is no excuse for bad work, surrounded, as we all are, by the highest examples. A fine translation of modern life appears to be growing in mural painting of the great type, and is heartily to be welcomed. In this connection, I would draw attention to Mr. Furse's work at Liverpool, and some of the work at Glasgow, while, in allegory, we have the great work of Mr. Sargent at Boston. In setting ourselves a standard we may remember, perhaps, the words of Puvis de Chavannes: "*Toute décoration ne peut être belle que dans la mesure où elle reflète la Nature et en traduit la passion.*"

NOTES & CLIPPINGS

TREES IN PARIS. — The annual cost of maintaining trees in the streets of Paris, where they alternate in rows with iron lamp-posts, is $90,000. There are 87,693 trees in the city of Paris growing in rows along the sidewalks, exclusive of the trees contained in the city parks, gardens and squares. A corps of tree-inspectors is constantly on the alert watching the trees. The soil is frequently renewed. Iron "corsets" are placed around young trees to protect them from injury. A circle at least three yards in diameter is kept free from asphalt or pavement around the base of each tree. This circle is usually covered with an iron grating, to preserve the proper level of the sidewalk. The trees are watered by the street hose twice a day. Excavations are made around the trees so that the water collects about the base of the trunk and percolates freely to the roots. The variety of trees planted along the Paris sidewalks comprises horse-chestnuts, elms, acacias, lindens, sycamores and the Japanese sumac. Horse-chestnut trees are great favorites with Parisians, because they come so early in leaf. The present spring is unusually advanced. The horse-chestnuts put out their leaves on March 17, and, notwithstanding the recent cold winds and rain, the streets of Paris are already fringed with delicate green branches. Ever since the Haussmannization of Paris began, fifty years ago, the French Academy of Science and the Health Department of the city have never ceased to impress on the Municipal Council the necessity of maintaining rows of trees along the main streets. The City Fathers fully appreciate that trees materially improve the health-rate of the population, by absorbing noxious gases and emanations, and by renewing the air breathed by the citizens. Paris has within the mural fortifications a population of 2,660,559 inhabitants. If the public parks, squares and gardens be included in the calculation, it will be found that in Paris there is at least one tree for every inhabitant. The official statistics, however, do not comprise trees planted in public or private parks, squares and gardens, but only those growing in rows along the sidewalks. The number of these trees is 87,693. That is to say, in the streets of Paris there is one tree for each 3.3 inhabitants. It might be interesting to ascertain how the six most populous cities in the United States compare with Paris in this respect. New York, with its population of 3,437,202 inhabitants, in order to reach the Paris standard of a tree for each 3.3 of its citizens, should have 104,158 trees planted in its streets, exclusive of those in public or private parks, gardens, squares or back-yards. Chicago, with its population of 1,698,575, in order to keep up with Paris, should possess rows of trees along its sidewalks containing 51,139 trees. Philadelphia, with a population of 1,293,697, should have 39,203 trees in its streets. St. Louis, with a population of 575,238, ought to have its streets lined with 17,431 trees. In order to compete with Paris in tree-culture, the 560,892 residents of Boston should have 16,997 trees in the streets, exclusive of those in the Public Garden, Common and parks and squares. Baltimore, with a population of 508,957 inhabitants, should have 15,423 trees in her streets. It is probable that some of these cities may already have attained or even exceeded the Parisian standard of one tree to each 3.3 inhabitants, but all interested in the question of municipal science will be gratified to learn that the tree-department of the city of Paris is felt to be of paramount importance for the public health, and the Municipal Councillors of Paris do not regard green foliage as a luxury, but as an absolute necessity. — *C. I. B. in the N. Y. Tribune.*

HOMESTEAD ENTRY CANCELLED. — The Federal land officials in Santa Fé, N. M., on March 27, cancelled the homestead entry of Richard Wetherell, of New York, upon orders of the General Land Office. Wetherell is manager of the Hyde Exploration Company, engaged in numerous enterprises in northern New Mexico, and had filed upon the Pueblo Bonito, Catro Kettle, and Pueblo de Arroya, three of seventeen prehistoric ruins in Chaca Cañon, Southern San Juan County. When he found his homestead entry did not quite cover the ruins he made an amended entry. The Hyde Exploration Company thereupon erected stone buildings on the land, costing $10,000, established a stage-line and hotel for tourists, and commenced excavating. According to a sworn statement made by Wetherell to J. S. Holsinger, special agent of the United States Land Office, he took out of the ruins 50,000 pieces of turquoise, 10,000 pieces of pottery, and many wooden and stone implements and skeletons, which were sent to the American Museum of Natural History at New York. About 500 rooms in the ruins have been excavated thus far, and 179 pit excavations have been made. The General Land Office cancelled the homestead entry because the land was not filed upon with the intent for which homestead entries could be made. — *N. Y. Times.*

LONG-DISTANCE HEATING IN GERMANY. — United States Consul-General Richard Guenther, of Frankfort, reports to the State Department the completion at Dresden, Germany, of the largest long-distance heating-plant in Europe. From a central station, says the Consul-General, many public buildings on the left bank of the River Elbe, including the theatre, the museum, the castle, the royal kitchen, the custom-house, etc., are heated. The greatest distance over which heat is transmitted is three-quarters of a mile. The total heat-consumption per hour is 15,200,000 heat units. The usual steam-pressure is two atmospheres. Ten of the fourteen boilers are used, and to guard against accidents two main lines of pipes have been provided. The loss of heat in transmission is from 4 to 4½ per cent. The pipes are protected by two layers of tin, the inner layer being perforated and the outer one covered with silk. The largest pipes have a diameter of 216 mm. (8.51 inches). — *Exchange.*

NOTES AND CLIPPINGS. 48

THE Boston *Herald* gives a very timely warning against an attempt which is being made to nullify the provision in the building-law which limits the area which can be covered by a non-fireproof building, without subdivision by brick walls, to eight thousand square feet. This is, perhaps, the most important and valuable provision in the whole law, and it is also the one which the owners of department-stores and other dangerous fire-traps have always fought hardest and most persistently against. Last year, certain iron-workers came to the Legislature, representing that the proper handling of their materials and machinery required larger undivided areas than eight thousand square feet, while the character of their business did not demand the steel-and-concrete construction with which alone, under the present law, larger areas may be enclosed. Any one who has seen the travelling-crane system of modern iron-working shops can understand the importance of sufficient space for their operation, as well as the smallness of the danger attending a reasonable extension of the limit in such cases, and the best experts were disposed to favor the relaxation of the rule, in the portions of the city outside the so-called "fire-limits." This year, however, new interests have taken up the matter, and the request of the iron-workers has appeared again in the form of a bill, which is now pending before the Legislature, and provides that not iron-working shops merely, but all buildings used for "working in or storing non-combustible materials," outside the fire-limits, shall be exempt from the provision limiting undivided area. It is hardly necessary to point out, as the *Herald* does, that "non-combustible" is a very elastic adjective, applicable to many substances which would be objectionable in case of a great conflagration; while even a building devoted to "working or storing" non-combustible substances may contain wooden work-benches, shelving and other combustible incidentals to a very dangerous extent; and there is always a possibility that a building originally intended for the storage or working of incombustible materials may, through change of ownership, or other causes, be utilized for working or storing inflammable materials. No law yet devised has been able to prevent changes of this kind, which constitute one of the principal sources of danger in ordinary constructions; and any modification of the building-statutes should have such a contingency in view.

THE New York Department of Buildings complains of the amount of unnecessary work imposed upon it in the examination, rejection and reëxamination of plans by incompetent or careless architects, who, in fact, are, in New York, rather disposed to depend upon the engineers of the Department to make the corrections in their drawings which they ought to be capable of making themselves. The problem is really a serious one, not only for the officials of the Department, but for the skilful and competent architects, whose carefully prepared plans are kept waiting, often for weeks, while the Department engineers are correcting the blunders of ignorant pretenders. Under the Tammany régime, a scheme was prepared for registering on the books of the Department such architects, builders and superintendents as should give proof of competence, by examination or otherwise, and issuing permits to build only to registered persons; but there were doubts of the legality of such a regulation, and it was never adopted. Various projects for licensing architects, or otherwise separating men of proper training from the ignorant and unskilful, have been brought before the New York Legislature, and some one of them may, in course of time, become a law; but, in the meanwhile, it seems as if needed relief might be afforded by an adaptation of the London plan, appointing several skilful and experienced architects in each borough to act as examiners of plans. Projects for building would then be brought before the examiner for the district in which the new structure was to be erected, just as all plans for building in London must be submitted to the District Surveyors; and the drawings would be received at the Department of Buildings only after they had been made satisfactory to the district examiner, and had been stamped by him. With only such plans to consider as had been approved by the skilled architects who served as district examiners, the duties of the Department engineers would be very much lightened, and the business of the Department could proceed with far more regularity and despatch than is now the case, to the great advantage of all concerned. The London District Surveyors receive from each person submitting plans for examination a small stated fee, and the same arrangement might be made for the remuneration of the district examiners in New York. In that way the city treasury would not be burdened with additions to its salary-list, and persons proposing to build would gladly pay a dollar or two for the sake of prompt examination of their plans, while this system would adjust the remuneration accurately to the work done. It is not to be expected, of course, that the district examiners would guarantee the perfection of the plans which they had approved, any more than the Department engineers guarantee, under the present system, those which they pass. In both cases the object is simply to secure the judgment of competent experts, and correction in conformity with such judgment, on all plans, before they are received at the Department, leaving to the Department the duty more properly belonging to it, of interpreting the law in cases of difficulty, watching over the execution of plans for which permits have been granted, and punishing variations from the drawings and specifications on file, and other violations of the law.

THE advantage of the modern steel-frame construction over the older style in point of rapidity has been strikingly shown of late. It is obvious that, while every portion of a steel-frame structure takes as long to make as the corresponding part of a building of masonry, it is possible, in the former, to prepare the parts outside, and, when they are ready, to "assemble" them, to use the apt expression of one of the most distinguished of the great contractors, with a rapidity which is out of the question in masonry structures. In costly office-buildings, the saving of interest and rent by shortening the period of construction is of great importance; and this, together with the increase of rentable floor-space afforded by the thin walls of the steel framing make this very popular with the owners of such property. For example, a fifteen-story building has just been completed in New York, in a little over five months from the time that the first basement column was set in place; and a contract is said to have been signed for the construction, within a similar period, of a banking building twenty-one stories high. In New York, office-buildings to the value of twenty-four million dollars, all of steel framing, are said to be in process of construction, and the demand for new offices exceeds the supply.

MEANWHILE, the anxiety of architects in regard to the durability of steel skeletons encased in concrete or masonry does not diminish. A steel-frame building, twelve years old, which was recently torn down in Chicago, is said to have had its lower columns eaten half through by rust, although the concrete casing around them was so thoroughly filled in, and so firmly attached to the steel, that it could only be removed in chips, each chip bringing with it a portion of the

Entered at the Post-Office at Boston as second-class matter

oxidized metal. We cannot vouch for the truth of this story, which contradicts almost everything that is known about the action of concrete on iron, but, if it is true, further investigation is needed at once. The collapse of a steel-frame building would cause something like a panic among the owners of the most costly mercantile and office buildings in the country; and, if the columns of such a structure have really been eaten half through in twelve years, some of the largest in Chicago, which are very close to their twentieth birthday, must be in a precarious condition. It might not be unprofitable for the insurance companies to take up the matter, and issue policies against loss by rust in steel-frame structures. Prudent owners, who are too sensible to risk their property in what is, in this respect, an experiment, would be very glad to pay a reasonable sum for a contract of indemnity; and the insurance companies would be able to study the subject more impartially and effectively than any one else. We do not know whether the American companies would be at liberty, under their charters, to engage in such contracts; but the English companies could do so; and, considering the immense sums of money at risk, and the comparative ease with which danger, if it is found to exist, can be averted, if taken in time, this branch of the business ought to be very profitable. It must be remembered that an insurance company has always at hand an efficient weapon for enforcing its orders, in the shape of a notice that a policy will be cancelled if they are not immediately complied with; and a few good inspectors, experienced in the effect of various circumstances on the mixed construction, and skilled in detecting symptoms of disorder, as well as in prescribing the proper remedy, might, within the next ten years, do incalculable service to real-estate interests, as well as to the insurance companies employing them.

THE explosion of the boiler in the factory of the Pemberthy Injector Company, in Detroit, which destroyed the building in which the boiler stood, and caused the death of thirty people, and injury to as many more, has been studied by experts, with very interesting results. From the report of Professor R. C. Carpenter, of Cornell University, which is published in *Power*, as well as from the verdict of the coroner's jury, it appears that the explosion was due to the bad quality of the steel in the boiler and the bad workmanship upon it. Not only were the sheets of thickness less than the three-eighths of an inch called for by the specification, but they were uneven in quality, portions being highly charged with phosphorus, and being, in consequence, so brittle that pieces could easily be broken from them with a hammer. The riveting was badly done, the rivet-holes in the two sheets in some cases failing to come opposite each other, and the space being filled with a small rivet, crushed down on each side by a power riveter, so as to present the appearance of a rivet of proper size. The fracture, however, was not through the rivet-holes, but irregularly parallel with them, and Professor Carpenter concluded that it was due, not to direct strain, which, under the careful management of the engineer in charge, did not exceed the safe limit, even for the thin sheets actually used, but to the brittleness of the sheets, which had caused them to crack along the line where their expansion and contraction would tend to bend them slightly, first in one direction, and then in the opposite direction. Flange steel of first quality, such as the specifications for the boiler required, would, it is needless to say, bear without harm an indefinite amount of bending of this kind, and the use of a brittle and phosphorized steel in such a place was, as most people will think, little short of criminal. The coroner's jury seem to have held this view, for, while they exonerated the Pemberthy Company, and its officers and engineer, from all blame in connection with the catastrophe, they held the makers of the boiler responsible for it.

THE old Colonnade Hotel, in Lafayette Place, New York, one of the most charming pieces of street architecture in any city, is to be torn down, and the Municipal Art Society proposes, if money enough can be raised for the purpose, to buy the granite Corinthian columns of the colonnade, and present them to the city, for use in some form in one of the parks. It is suggested that they might be utilized to form a screen, to hide the tracks of the Sixth-Avenue elevated railway from Bryant Park, on which the great New York Library is now in process of construction. If it should be impracticable to set them here, there are plenty of other places in the New York parks which they would adorn very effectively.

THE award of the annual Royal Gold Medal by the Royal Institute of British Architects has been disturbed this year by the death of its destined recipient, Mr. Bentley, just before the formal award. The Council of the Institute suggested that the medal might be given to Mr. Bentley's family; but the King, to whom this suggestion was submitted, very politely, but decidedly, objected to it, on the ground that such an award would form a dangerous precedent. The Council of the Institute will be obliged, therefore, to find a new candidate.

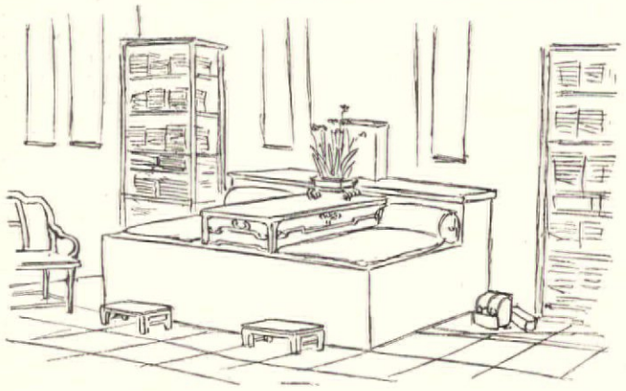
MR. BENTLEY, the architect, who, if he had lived, would have been recommended for the medal, was almost unknown to the profession in this country, but his originality and a certain breadth and force in his designs, have long been greatly admired by architects in England. Being of a reserved, and rather eccentric, disposition, he rarely figured in the great competitions, or as the architect of noted public buildings, and his talents were devoted almost exclusively to the service of the Roman Catholic Church, of which he was a devout and zealous member. He made and executed many remarkable designs for ecclesiastical buildings of various kinds for this Church in and about London, and it is very much to the credit of the Royal Institute that its officers should have chosen for its highest honors an artist so little known to the public, in place of men of much more conspicuous worldly position.

TWENTY-FIVE or thirty years ago, Viollet-le-Duc was sent to restore the ancient walls of the city of Avignon, once the fortified residence of the Popes. According to his own account, there was not very much left of the original walls, but, with what still remained for a pattern, he was able to construct on the old foundations an extensive and imposing specimen of mediæval fortification. Although the long ranges of lofty, crenellated walls produced a great effect upon tourists, they were not, after the novelty had worn off, entirely charming to the inhabitants of the city, who found the space within the fortifications becoming crowded, and did not like the idea, if they built themselves houses outside the walls, of having to make a long circuit, in search of a gate, whenever they had occasion to enter or leave the older part of the city. They represented to the Government the importance of having the walls removed, in order to allow the city streets to be extended; and, to meet the sentimental objection, that this would involve the destruction of an ancient monument, they pointed out that the greater part of the walls, having been the work of Viollet-le-Duc, could only be considered an ancient monument by a violent effort of the imagination. The application of the citizens was received, and submitted to long discussions. Some people sympathized with them; while others held that Viollet-le-Duc's work, being the completion of an ancient monument fallen to decay, was really a part of the monument, and shared its sacredness. Between the two parties nothing was done; and, as the population of Avignon increased meanwhile, and the need of more space for houses became greater, the Mayor of the town, M. de Boisserin, determined to take the matter into his own hands. He did not dare to interfere openly with the walls, which are State monuments, and, as such, under the jurisdiction of the Prefect, who represents the State, in distinction from the municipal authority; but, one evening, he invited the Prefect to dine with him, and, to make sure of his guest, went to his house for him. In the meanwhile, he had prepared an order, directing the immediate demolition of the Porte Limbert, one of the most objectionable portions of the fortifications, and had made sure that a sufficient force of workmen should be ready to carry it out. While the Mayor and the Prefect were at dinner, the order was issued, and a copy, as the law requires, was sent to the prefecture for the approbation of the representative of the State. As this official was, at the moment, comfortably dining with the Mayor, and no one thought it necessary to forward his letters to him, he was unable to make the protest which he certainly would have made if he had known what was going on. In the meantime, however, forty men were busily at work on the Porte Limbert. Late in the evening, the Mayor invited his guest to take a walk, and led him to the place where the Porte Limbert had been. The Prefect lifted up his hands in horror at seeing a monument of the State in ruins; but it was too late to object, and the Mayor, coolly avowing his part in the transaction, and the reason for it, conducted his afflicted friend home. What punishment was inflicted on the Mayor for his audacious conduct we are not informed, but it seems probable that the prayers of the citizens of Avignon in regard to their walls will receive more attention than they have had hitherto.

JOURNAL SKETCHES IN CHINA.[1]—II.

Foot-warmer.

WITH this digression let us return to our Chinese family. This my first critical visit to a Chinese home was made on a cold and rainy day in February; there was no fire in the house and no visible means of providing warmth, the apartments were dark, damp and chilly, the floor was wet and cold, and I began to stamp my feet to get warm, upon which a servant brought me a bronze foot-warmer. Despite this I was compelled to wear my thick winter ulster during my stay. It was, indeed, a unique opportunity to be in a gentleman's house the entire day and see the full round of domestic economies, cooking, washing etc., going on without disturbance save what my presence excited. The library-room was very formal and stiff in appearance; the place for reading or study consisted of a raised floor which projected like a square block from the



Library: Private House, Shanghai.

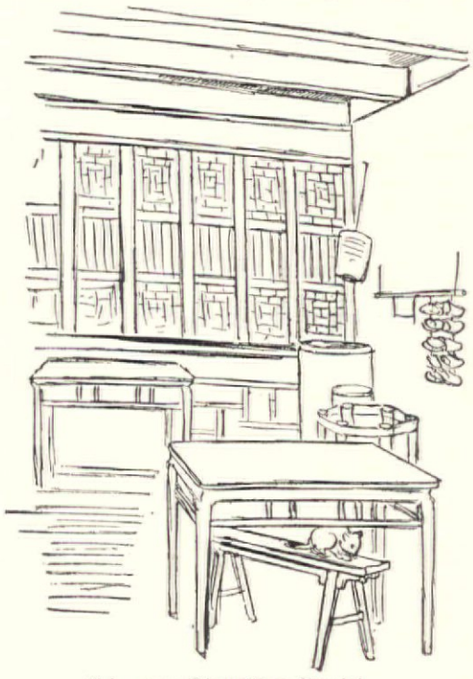
middle of one side of the room to a distance of from 7 to 8 feet. A higher portion next to the wall formed a shelf a foot or more in width; resting on the projecting portion was a long, low, narrow table running out at right angles from the wall, leaving a space 3 feet wide on either side; this space permitted a reader to recline at full length or to sit on the edge of the platform resting his feet on a low stool at the end. Book-shelves were against the wall on either side of the platform and on the wall were hung long, narrow kakemono, on which were inscribed precepts from Confucius or some other revered sage. The accompanying sketch will best illustrate the arrangement above described: At the side of the main entrance of this room was a writing-table upon which was a tray containing a brush-holder, inkstone, a Chinese water-pipe and other conveniences, and here one of the young men sat while I made a hasty sketch of him. On each side of the room, against the wall, was a square table, with a chair on either side in touch with the table and the wall. It looked very stiff and formal. During my inspection of these details a little sister of my host came into the room; she was exceedingly shy and held close to her brother. I tried to induce her to come to me, but though she smiled at my attempts in a frightened way I could get no farther in my advances; whereupon I proceeded to make a sketch of her, she, meanwhile, looking very dubious and clinging to her brother all the time. The band over the front of her head was a thick affair of black silk richly embroidered in pearls mounted in gilt; the stuff from this, hanging over her forehead and looking like a bang, was composed of black silk thread. The hair behind was wound up in two compact pugs which were secured in some way on each side of the head; her ears were rather large and the outer margin had two perforations, and at the time held two simple gilt rings. She was very pretty, ten years old and the daughter of a Chinese gentleman, and yet when I asked her brother to induce her to give me an autograph on my sketch he told me, in the frankest way, that she could not write and that girls were not taught to read or write. Here was another startling contrast to the Japanese which English writers, of course, recognize as an evidence of the superiority of the Chinese. I particularly noticed the little compressed feet of the girl, and while sketching her an aunt passed through the room with the gait that reminded me of a goat or one walking on very short stilts. They do not limp, but simply stump along.

Writing-table, etc.

Every one that I saw in the house was clothed in thickly quilted garments and my entertainer wore a fur robe besides. It was true I was chilled to the bone in my thick winter ulster, and from my short experience it seemed to me that the Chinese city-house, though having thick brick walls and closed doors, was as cold as the Japanese house, with a chill which the latter does not possess and dirt which only an Ainu hut could parallel.

My host and his friends were dressed in the ordinary costume of the better class of Chinese, and, curious to know the cost of their clothing in order to compare with that of our own, I made bold to ask my host the price of everything he had on at that moment. He showed no surprise at my curiosity and gave me *seriatim* a list of the prices which had been paid for the clothing, which he assured me, represented the daily garments of a young man of his class. Long overcoat lined with squirrel-skin, $35; short satin gown, $60; waistcoat, $4.00; leggings, $3.00; sleeves, $1.00; stockings, 20 cents; hat, 50 cents; wadded gown, $5.00, and a few other items brought the sum to $110.70. He further informed me that a finely dressed Chinaman might easily have on clothing costing $1,500.

From the study we entered a large dining-room, possibly 20 feet



Dining-room: Private House, Shanghai.

square. It was dimly lighted like all the other rooms, gloomy better describes it, and cold and damp besides. In this room were various tables, chairs, a case of large drawers, a cupboard and a number of well-constructed benches, in form not unlike a "carpenter's horse," only made of a dark, hard wood and finely finished. Among other objects was a baby's chair made of a stout bamboo in the form of an octagonal tube with a partition half way down upon which the baby rested. It was as brown as an old meerschaum pipe from age and grime. Dirt and disorder were in evidence here as elsewhere in the house. The windows had a complicated framework, too intricate to hastily sketch. The formula for the window-frames struck me as the same over a wide region in China. I saw the same at Canton and have seen photographs of buildings in other places in which the same design appears. The dining-room opened directly into a yard behind the main house, and across this yard, at a distance of 15 feet, was the kitchen, a narrow tiled roof extending across the yard from the dining-room door to the kitchen door. Under this roof an old woman sat astride a bench washing clothes in a large shallow tub, which also rested on the bench. The windows of the kitchen had close, net-like wooden frames covered with paper, as in the Japanese *shoji*, but all the little squares were broken through and there was no evidence that any attempt had been made to repair them, and this neglect in a fine house, too. Again, the contrast with similar conditions in Japan, where if by accident a hole is made in the *shoji* a bit of paper is cut out in the shape of a cherry or plum blossom and the hole is patched with this tasteful device. Even in the poorer houses in Japan this dainty way of mending rents is often seen. Nowhere in the house

[1] Continued from No. 1372, page 13.

did I see the evidence of any attempt having been made to repair or to prevent matters from going to rack and ruin.

While the window-frames in the kitchen and out-buildings consisted of a close framework covered with paper, in the house proper, many of the windows were made of vertical slats of bamboo, 3 inches apart, to which were tied the thin, translucent shells of a species known as

Back-yard of House, Shanghai.

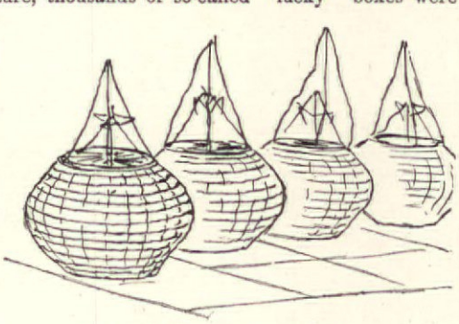
Placuna. These shells are flat, circular, and are trimmed into a rude square and perforated at the edges, so that they may be tied to the bamboo frames. The shell admits only a dim light and represents the window-glass of China. The use of this material by the Chinese is a good illustration of their conservatism. Window-glass can be cheaply purchased in the foreign concession, yet the usual contempt that the Chinese holds for anything foreign confines him rigidly to this archaic device. The kitchen was dark, gloomy and dirty. It was anything but appetizing to see so much dirt and to remember that here was to be prepared the dinner I was invited to eat. The stove was a curious affair. It was made of brick and plaster and occupied considerable space in the room. Three large iron pots in line were permanently built into the structure and two smaller pots were built near the chimney. Many of the Shanghai kitchens had chimneys — a feature rarely seen in the Japanese kitchen. The opening of the stove was behind, and here the wood was piled for the fire. In the chimney above the stove was a shelf-like recess on which was a candlestick, and on the side of this recess was suspended the kitchen deity, as well as conveniences for burning incense. The floor of the kitchen was paved with small bricks and these were grimy with wet dirt. There was no scraper nor mat at

Kitchen Range, Shanghai.

the door and the inmates did not remove their shoes for indoor slippers. So far as I could see, the mud and filth of the street were tracked into every part of the house. The rooms were all high-studded, much higher than our rooms at home, but the walls and ceilings were discolored with dirt and grime. Back of the kitchen was a long, narrow closet-like room, in which were a number of lanterns hanging from a rope, a few shallow tubs leaning against the wall, and at the farther end a niche in the wall holding some small jars. Even in this shed-like place facing the dirtiest of yards the window-frames were of intricate patterns. In the sketch of the kitchen what appears to be a table is in reality a chopping-block supported on four legs. In Oriental kitchens a large chopping-block or plank is always seen, and the sound of the rhythmical blows as the cook, with a knife-like chopper in each hand, beats a tattoo is a characteristic of Chinese as well as of Japanese houses. In this kitchen, as in other kitchens I saw, clutter and dirt had the upper hand. Baskets, pots and dishes littered the table as well as the little table beneath. There were no chairs in the room, but long narrow benches such as have been already described. The floor was also littered, and confusion and damp dirt pervaded the place. Indeed, if I pause for a sentence, the appalling character of the dirt, not ordinary clean dirt, but what appeared to be pathologic dirt, intrudes itself and I have not done the matter justice. I must admit, for fear of doing the Chinese an injustice, that the contrast was the more pronounced having just come from Japan, where the shoes are always removed before entering the house, the floors and mats are repeatedly swept, and the woodwork of the rooms and the floor of the veranda are often wiped with a damp cloth.

In one room we passed there had just been brought in four large straw baskets fresh from the maker. These were as big as large pumpkins, and had a light framework of wicker above, evidently made after some definite formula. The baskets seemed too frail to bear the usual treatment accorded these archaic yet beautiful devices. On inquiry, I was told that on the anniversary of the death of some ancestor one of these baskets, filled with gilt paper representing money and bought by the peck at a neighboring shop, is burned at the grave.

One notices at the doorway of shops, at the gateway of a city and at other places little piles of ashes on the ground, an evidence that joss-paper, as the foreigner calls it, has been burned as a propitiatory offering, or to ward off evil influences. One feels an extreme contempt for a people guilty of such superstitious and ridiculous practices until he recalls the various superstitions and credulities which characterize his own race. Only a few years ago, in Boston, that centre of intellectual culture, thousands of so-called "lucky" boxes were sold. These were said to have come from India and to be endowed with some peculiar property whereby the possessor would secure good luck, and many testimonial letters were published showing their marvellous potency. The city authorities finally stopped the sale of them as fraudulent, and then it was discovered that they had all been manufactured in Lynn, a neighboring town, and the only property with which they were endowed was the sweat of two overworked wood-turners. Thus much for credulity. Indeed, if we but stop to enumerate the number of superstitions believed in by our own people the list would almost parallel that of the Chinese, who are supersaturated with them. As a proof of this we have only to recall the appearance of an otherwise rational American backing out of his front door in order to see the moon over his right shoulder, or the sight of a man stepping into the mud rather than walk under a ladder, or a hungry man missing a good dinner to avoid making thirteen at the table. An equal absurdity is to see an apparently sensible man draw from his pocket a handful of change with which is a well-worn rabbit's foot. These and many other superstitions will readily suggest themselves to every one. As a matter-of-fact, we grow up with our superstitions and our methods of lying and are no longer impressed by them. We visit a new country and the novelty of the superstition or lie arrests our attention and we moralize about it.



Baskets with Paper to be burned at Grave.

At one side of the court-yard was a high, narrow opening having two doors, one off its pivots. This led into a narrow yard surrounded by high walls. The ground of this yard was paved with stone, and against one of the walls was a brick pen, 4 feet wide, 15 feet long and 3 feet high — very much like a cellar coal-bin. This was filled with earth and represented the flower-garden of the estate, doubtless an attractive feature in the summer, but now presenting only a few dry stalks and dead leaves. It certainly looked dreary enough. Two little children from the neighborhood had kept close by me during my rambles and by pantomime expressed a wish to be sketched. Afterwards one of these little fellows made certain motions to my host, at the same time pointing to his companion's head. I inquired why he was gesticulating in this way and was told that he was trying to tell us not to go near the boy, as he had parasites in his hair, and he was warning us as quietly as he could so as not to offend his friend. In this act there was certainly betrayed some sense of cleanliness as well as consideration for his friend's feelings — a trait for which the Chinese have been given little credit.

While in the house I was somewhat surprised to have an opportunity to sketch a slave. Those who are familiar with the literature of China know, of course, that servants are bought and sold; yet to see a veritable specimen of humanity that had been bought like a piece of merchandise was, to me, a novel experience. My host brought the girl into the room to be sketched and informed me that she had been purchased in Canton some years before. The price paid was $60 in our money, but with the instructions she had received in household duties (which certainly did not include sweeping and cleaning) she was worth at least $200. In thus holding the girl as a slave the master conditions that she shall be married off when of a marriageable age. How meekly this poor creature stood when I sketched her; patient, apparently uncomplaining, literally knowing nothing about her antecedents, doomed to work and slave as long as life lasted, whether single or married. With the degradation of women in China it is possible that her lot might be considered far happier than that of her mistress in that she had her two good feet to stand upon and could see the activities of the street without impropriety. It was, indeed, a hard lot. The old African slave, with his dances and songs, freedom in the open air, and 'possum hunting on a moonlight night, might be considered in a state of bliss and wildest freedom compared to the lot of a female slave in China.

After ransacking the house for an hour or two, dinner was announced. The table, for some reason, probably on account of the clutter in the dining-room, was placed in the study. It was of dark polished wood, 4 feet square, the legs square and slender, with the curious open-work between them, so characteristic of Chinese furniture. A seam ran through the top of the table where the two boards joined. In seating guests etiquette requires that the seam should run at right angles with a line drawn between the host and guest. We were four in number and the first guest of honor sits directly opposite the host, the next in honor sits at the left of the host, while the third guest sits directly opposite the second guest, and, of course, to the right of the first guest. Women are excluded from the table as in Japan. The tables are not placed together, but, if there are more guests, additional square tables are provided, which are placed in different parts of the room; probably definite places are assigned to them, though about this matter I failed to inquire.

Wine and oranges were first offered us; the wine a *sake*, much finer than I had drunk in Japan. The dishes of food were placed on the table in a radially symmetrical manner. No plates or individual dishes were provided until the rice was served, and then each one had a bowl to himself. Each one helped himself to whatever he liked from the assembled dishes. In one dish was a fish with rich gravy, and each person picked in turn from it. This, of course, is done with the chop-stick, and my ready use of these "nimble lads," as they are called in China, led my host to remark upon it. Following is a list of the articles of food which we had for our dinner, with my brief comments recorded at the time: —

Water-chestnut. Crispy and interesting.
Peanuts, fried in oil, served cold. Delicious. (Will fry peanuts when I get home.)
Watermelon seed. Indifferent, and one wonders what the Chinese find of interest in the diminutive morsel within.
An uncooked goose's egg, four years old. Ghastly.
Salted chicken, cold. First rate.
Salted pork. Fairly good.
Clover-leaf and bamboo. Not unlike spinach. Delicious.
Fish with rich gravy. Delicious.
Shark's fin, a gelatinous mass. Delicious.
Fermented bean-curd soup. Very poor.

I was surprised to find that nearly all the articles of food were not only good but appetizing so long as the recollection of the kitchen did not obtrude. In justice it should be said that not one speck of dirt or foreign substance showed itself in the various foods; no suspicious fragments of an insect, no gravel in the clover-leaf, as one often finds at home in his spinach and lettuce. With the usual reversal of things Chinese, the kitchen is dirty, while the food is clean. Judging from the first experience, Chinese food resembles in taste our own far more than does that of the Japanese. One has to acquire by practice the enjoyment of many kinds of Japanese food. Of course the foreigner takes at once to the Japanese raw fish, with its sauce, which must have been specially created for the fish; the rich custard-like *chawan-mushi*, the fried eels, and many other delectable preparations. The Chinese food appeals to one at once. The fish, with its rich gravy, and the salted meats were not unlike ours, the salted chicken was remarkably good, and I would suggest to our farmers that they prepare a barrel of corned chicken just as they prepare a barrel of corned beef. Chicken and turkey might easily be preserved in this way for transportation.

While gnawing my chicken I wondered what I should do with the bone. It would not do to lay it down on the polished table-top, I certainly was not expected to return it to the communal platter, and there was no individual plate, so in despair I was constrained to ask my host, and he told me to throw it on the floor, which I did. Indeed the floor, judging from its appearance, fulfilled the function of slop-pail, cuspidor and garbage-barrel combined. When one considers the dirt tracked in from the street on a wet day with no conveniences for removing it before entering, it will be readily understood that the débris from a dinner would add little to the dirt already accumulated. In some ways one was reminded of the savage Ainu hut, where the inmates eat out of the same dish and fling the bones on the earth floor. The conservatism of the Chinese must have begun back at the dawn of their emerging from quadrupedal ancestors; for this reason one finds projected into their present life many archaic survivals. Their fiendish cruelty; their innumerable childish superstitions; their propitiation of unseen evil spirits and influences; their filthy manners, and, above all, their absolute indifference to ascertain the causes of phenomena must be regarded as survivals from their prehistoric savage ancestors.

The goose's egg was a revelation to me, and the dainty way in which my Chinese friends ate crumbs of this awful substance probably has its parallel in the way we nibble our stronger cheeses. The raw egg is allowed to go through every stage of fermentation, putrefaction and whatever other unimaginable processes of putridity it might venture upon. These changes take place while surrounded by a thick coating of clay. The egg may be one year old or ten years old; conceive for a moment a rotten egg even four years old! It resembled a green variegated soap and had a greasy crumble to the touch and tasted as one might imagine the condensation from the inside of a charnel-house might taste. It was ghastly and one taste of it lasted me a week. My Chinese companions were nibbling crumbs of it, not mouthfuls, as I observed. On my expressing a certain amount of horror at the idea of eating a rotten egg four years old they quite justly reminded me of our Rochefort, Brie and Limburg cheeses, equally ghastly to them. They were evidently familiar with the processes of making our stronger cheeses, for my host recalled the process of cheese-making by saying, "Which is worse; a fairly rotten egg three years old which has never been removed from its first shelly enclosure or a liquid substance derived from a modified sebaceous gland of a cow to which is added the active principles of the gastric juice of a young calf?" He further went on by reminding me that in the case of the stronger cheeses this stuff is put in a skin bag and buried in lime, so that it will not go entirely to the dogs; in the case of Limburg it is actually permitted to putrefy. Some of the cheeses are kept a year or more, and we do not hesitate to eat them when green with mould, as in Rochefort, and even fly-blown, with wriggling maggots within, and yet smack our lips over them! I had nothing to say and had to confess that a bad egg three years old was a fresh dainty tid-bit in contrast to the substance he had so graphically depicted.

Returning to our menu, I would suggest that our people learn to cultivate the delicious clover-leaf, ginger-shoots and other delightful forms for our salads. Ginger might be successfully cultivated under glass, and the young shoot is most delicious.

After dinner we left the house by a back-door and passed through a large back-yard. In this yard was a huge mound, at least 25 feet high, composed of brick, plaster, broken roofing-tiles and ashes. I thought at first it corresponded to the *Ko-yama* (little mountain) of the Japanese garden, but was told that, years before, an extensive conflagration had occurred in the neighborhood, consuming many of the houses, and the débris of this calamity had been gathered here as the only available place for its disposal. By what right this huge pile of rubbish had been placed in this particular back-yard I did not learn, but reflected that there was no other place that it could be carried to. It could not be thrown into the shallow river, as it would impede navigation; all the land surrounding the city was under cultivation or occupied with the innumerable sepulchral mounds; it had to be piled somewhere, and as this was the only open lot in the vicinity it was piled here. On the top of this mound two depauperated trees were struggling for existence, and from this vantage-point in a raw, cutting wind I secured a sketch of the house-tops in the immediate vicinity. How the Japanese would have utilized for beauty a mound of this size, and yet here was this pile of rubbish without even steps, and the two trees on top were evidently fortuitous. The house-tops present a somewhat uniform type of architecture and reach a nearly uniform height, with small, low chimneys. The walls were of brick and plastered outside, forming a marked contrast to the thin wooden and inflammable buildings of the Japanese. The ridges of the roof were ornamented with flat tiles placed on end as books are arranged in a rack and apparently without being fastened; at the ends of the ridge iron pieces were turned up against which the tiles rested. The firmly turned gables and heavily tiled roofs gave an appearance of solidity and durability.

A short walk from the house brought us to the jail, always described in books as an inferno. It was certainly a painful place. Here were collected a number of malefactors, dirty and dejected-looking vagabonds. There were two thieves in low wooden cages. The worst-looking device was an arrangement in the shape of a high wooden cage in which the criminal is imprisoned for a certain time. His head is secured through a hole in a plank which stands vertical and forms part of the cage. Friends are allowed to feed him, otherwise he would be permitted to die of starvation. He cannot lie down and if he drops to sleep has to hang by his head. This probably gives him but slight annoyance, however, as the Chinese absence of feeling is such that they are said to endure the most frightful surgical operations with little manifestation of suffering. One authority, in describing their peculiar insensibility in these matters, avers that a Chinese can sleep soundly while reclining across the top of a wheelbarrow with head bent back at right angles, mouth gaping and full of flies. However this may be, the annoyances that set most of us frantic do not seem to disturb a Chinese in the least. The punishments are frightful in their cruelty. My companion admitted that the wealthy and influential often escaped the severer penalties imposed by the law. He further told me that in case of matricide or parricide every

member of the murderer's family, including all the generations from great-grandfather to nursing infant, are put to death. Even the first-cousins are sacrificed and a school-teacher is impartially included, as he was influential in the formation of the boy's character. On expressing incredulity at such monstrous acts of injustice my informant insisted that this comprehensive punishment had been inflicted within ten years.

Coming out of the city gate that night I saw an emaciated beggar lying prone in the mud and slush at the side of the crowded thoroughfare. He was trembling and apparently in the last stages of dissolution; an empty basket was beside him for the pittance he hoped to attract by his pitiable condition. In that hurrying throng no one seemed to notice him. Such heartlessness was difficult to understand until one learned that if any one rescued such a case he would be held responsible for the man's debts and, possibly, for his crimes. It was certainly a shocking sight.

Such dirty booths as we passed with such dirty food for sale! Among the common classes, at least, there seems to be no attempt to make the food look tasty and attractive as in similar places in Japan. All of the messes not only looked unsavory, but some of them appeared positively disgusting. EDWARD S. MORSE.

ROMAN AND ROMANESQUE FRANCE. — I.

LYONS.

FRENCH folks are eloquent in their criticism of London fog and the British climate in general, and with reason; but at the same time it is well now and then to look at home when criticising our friends, their ways and their works. Thus it has befallen me to visit Lyons on two occasions, each one in springtime, when one expects

Interior of St. Nizier's, Lyons, France.

in most parts of France to meet with fairly good weather; but Lyons seems to be an exception, and, be it not told in Gath, one's friends, whose misfortune it is to dwell in or near that city, give it a very bad character in its climatic arrangements. My experience is no better. I have been told by my *Murray* that one can see Mt. Blanc from Notre Dame de Fourvière; well, I have, like the pilgrims, climbed that mountain on foot, but nothing have I beheld but fog — fog below, fog above, fog everywhere. Yet, in spite of mist, mud and misery, the city impresses one by its situation and its fine rivers, which meet at one end of it, but are no more reconciled than the Catholics and the Free-thinkers, of which Lyons has not a few. It is a city of squalor and handsome houses, of beggars showing every deformity and masses of sores, and business men who certainly look well-to-do. Almost prehistoric carts rumble along and get in the way of steam-trams, as in most French towns — probably it is considered now a work of supererogation to reform the former while motors are, metaphorically, in the air; and just as the Rhone and the Soane march along side by side, the one exquisitely clear, clean, transparent and limpid, the other muddy, dirty and squalid, so the new church on the top of the hill asserts itself in all its blatant meretricious architectural taste, while beneath it a little gem of antiquity nestles in between some quiet streets, almost unseen, and, so far as I could discover, its tower only has been photographed. This relic of the great Abbey of Ainay possesses four huge granite columns, which may have belonged to the altar erected by the Gauls at the confluence of the two rivers (which originally joined their forces near the Abbey) in honor of Augustus, who resided in the city for some years. The pillars were evidently cut in two to form supports for the central cupola, probably in the twelfth century, or earlier, for the foundation of the church dates back to the year 937, and the monastery preceded the present building. The crypt is of the ninth century, and below the sacristy are some dungeons where Pothinus and Blandona were imprisoned before their martyrdom under Marcus Antoninus in the year 177. The bishop died in the dungeon; Blandona, the slave, suffered a worse fate in the amphitheatre, torn to pieces by wild beasts, bathing the soil of Lyons with her blood, as afterwards was the fate of Catholics and Protestants under kings and commoners. Possibly, few cities have seen more blood spilt upon her soil than Lyons. Political quarrels, religious squabbles, the modern strikes, have all furnished her history with martyrs.

It is said that the Augustan altar above referred to included a school of debate, or athenæum, and that unsuccessful candidates for its honors were beaten, thrown into the river like their successors under the Convention Nationale, or made to lick out their rejected effusions with their tongues. Thus Lyons began early in life to soil its history with various kinds of atrocities.

The church of Ainay has been much restored, but one can trace Roman brick intermingled with stone, and the form, as well as the terra-cotta ornament of the tower, are presumably Carlovingian.

The position of Lyons, surrounded by rivers and almost encircled by hills, must be most beautiful on a fine day. The highest point is crowned by the votive Church of Notre Dame, occupying a site which has been held sacred from the earliest periods — Forum Vetus (Roman), Fort Viel in the fifteenth century, and Fourvière in modern times. The only interest in the church itself is its profusion of good materials — marbles, mosaics and paintings offered by the devout instead of tablets or miserable works of art (?) such as one sees in most churches and chapels devoted to miracle-working saints or Our Lady. Here all is sumptuous and costly, if in bad taste and approaching the vulgar; but if it be possible to propitiate the Almighty for the sins of their ancestors by the practice of self-denial, the Lyonnais have certainly left nothing undone as regards wiping out atrocities unnamable by a costliness equalling that of Solomon's Temple.

The church occupies the exact site of the Forum Vetus erected by Trajan. Roman remains have been unearthed during the necessary excavations for the modern church — notably some arches of an aqueduct at the fort of S. Irénée. The modern church bearing that saint's name was erected upon the spot where she suffered martyrdom, and in the vaults the traveller may picture to himself the spot where the early Christians worshipped and suffered under Septimius Severus in 202. The Calvinists destroyed the older church, but in the crypt may be seen a well down which, it is said, the bodies of nineteen thousand martyrs were thrown, "until the blood overflowed," as saith tradition.

In the cloister of the Museum (the ancient Convent of S. Pierre, of which the church with its Romanesque portal is all that remains) are many marbles, fragments of votive tablets, *cippi*, altars, pavements and other Roman "documents." Also the bronze tables upon which we read the speech made by Claudius in the Senate (A. D. 48) when he moved that the people of Gallia Comata should be enrolled with the privileges of Roman citizens. (Claudius was born at Lyons on the day that the altar of Augustus was set up.) One of the pavements represents the gates from which chariots issued for the races; another, the taming of wild beasts by Orpheus. In the picture-gallery is the famous Perugino which was "given" to the city by Pope Pius VII; in other words, it formed part of the loot which Napoleon ordered to be carried off from Perugia, and which by sundry and divers subterfuges was withheld from the general restoration of works of art to their rightful owners by the Allies.[1]

In the suburb of Vaive may be seen all that remains of the great escarpment cut, *incisa*, by Agrippa for his military road. Here also stood the castle of the Archbishops (which was practically a prison) demolished during the Revolution. In it Il Moro (Ludovico Sforza) was confined by Louis XII before he was removed to Loches, where he died of cruel treatment. Cinq Mars and De Thou[2] were also imprisoned in the fortress, from which they passed to execution in the Place des Terreaux.

Lyons possesses in its Hôtel Dieu the oldest hospital in France, founded by Childebert, but remodelled by Soufflot, the architect of the Paris Panthéon, and later architects. Its plan is a Greek cross, with an octagon altar under the central dome, which may be seen from each ward. Upon a hill below Notre Dame de Fourvière is another interesting hospice, that of L'Antiquaille, which occupies the site of the Roman palace where Claudius and Caligula were born, and was a part of the ancient city of Lugdunum (Lucei Divnum), founded by Munatius Plaucus (B. C. 40), and the residence of Augustus and Severus.

The aqueduct, constructed by the soldiers of Marc Antony to supply the town with water from the mountains of La Forez, may be

[1] See *American Architect* for March 16, '01, "*Perugiano.*" By G. C. Williamson.
[2] A long account of their execution is given in a novel by Alfred de Vigny.

traced for miles by its broken arches, the most important fragments being at Bionnat, Chapponoet, Chardonniers and Oullins. (Of this fact I cannot add my own testimony in consequence of fog and rain.) Agrippa's four great roads radiating from Lyons to Marseilles, Paris, the Pyrenees and the Rhine may also be traced. The church of S. Paul is an interesting Romanesque building with additions of thirteenth to fifteenth century styles, the Flamboyant predominating. The interior has the original round arches, solid single-shafted columns and an octagon cupola, but, being given over to restorers, close inspection was difficult.

S. Nizier's is also interesting, showing Flamboyant details built on to a thirteenth-century foundation. The bays of the nave and the clerestory are part of the original church, the Flamboyant triforium having the appearance of being wedged in between them. The west front has a specimen, a still later style, patched on, a very fine but quite incongruous portal by Philibert de l'Orme.

Note also the Romanesque portal of S. Pierre with its billet moulding and the remains of an arcading in the same style on the west side of the archbishop's palace.

The Cathedral and other buildings (Hôtel de Ville, etc.), though most noteworthy and interesting in their distinctive styles, do not come within the scheme of this article. S. BEALE.

[To be continued.]

EDWARD R. SWAIN.

THE architectural profession on the Pacific Coast has suffered the loss of one of its leading members. Edward R. Swain, Fellow of the American Institute of Architects, died suddenly April 10, in San Francisco, where he was born fifty years ago.

He received his professional training in the office of David Farquarson, at that time the most prominent architect of his native city, and started some twenty-five years ago in the practice of his profession. Without academic training and having spent his entire life, with few interruptions, on this coast, he succeeded in associating his name with a number of buildings which stand out as attractive features in the rather uncouth architectural physiognomy of the Queen of the Pacific. He no doubt possessed in himself, and could detect and use in others, that complex compound of qualities which makes the good architect and manifests itself in buildings of fitness, substantiality and beauty.

The structures which constitute the life-work of Mr. Swain make impressive the fact that he had the peculiar gift to treat the material and to express the purpose of a building in a truly characteristic manner. All the buildings in which he had a chance to show his metal are good in sense and taste, and particularly free from sham. This deserves special acknowledgment in view of the fact that the majority of the architects in California in order, no doubt, to gratify the undeveloped tastes of their clients, fake wood, tin and plaster into all kinds of strange materials and unwarranted forms. As his chief works, in consequence of their substantial character, will enjoy a long life, the good example given by Mr. Swain will permanently benefit the profession on the coast.

Among the notable commercial and public buildings he has designed are to be mentioned the H. S. Crocker Building and the Hobart Building, both in granite, limestone and brick, well blended in color, the Goldberg-Bowen & Co. store building, the Park Lodge in Golden Gate Park, all excellently treated in form. After the death of Mr. A. Page Brown in 1895 he was called in to re-design, superintend and complete the Ferry Building, the largest structure of its kind in the world. Its tall clock and light tower, seen from nearly every point of the bay and the city, forms a conspicuous landmark, and its graceful outline stands to the credit of Mr. Swain, who took considerable pains in its re-designing. He was further prominently engaged in the architectural creation of the Midwinter Fair of 1894, for which he designed the highly picturesque Mechanical Arts Building in Indo-Persian style.

Praise is also due for his residential work. A great number of good, comfortable dwelling-houses all over the coast have been built after his designs, of which Mr. Wm. F. Whittier's residence ranks easily among the most substantial, best appointed and most refined in San Francisco. At the time of his death he was chiefly occupied with plans of a palatial residence for Mr. F. W. Macfarlane in Honolulu, where in the last years he erected a number of extensive commercial buildings, factories, etc.

In the prime of life and in the midst of a fruitful activity his career was cut short. In premonition of the fatal issue of an operation which a complication of diseases made necessary, he bequeathed his rich library and well appointed offices in San Francisco and in Honolulu to Messrs. Clarence R. Ward and Walter E. Pinkham, his professional associates for years, now his successors in California and in Hawaii, respectively.

Edward R. Swain left this world mourned by all who knew him intimately as a thorough gentleman and a dignified representative of his profession. M. J.

THE CITY OF MEXICO'S SEWERAGE SYSTEM. — By the end of this year the capital of Mexico will have a sewerage system covering the whole city. — *Exchange.*

SOCIETIES

DETROIT ARCHITECTURAL CLUB.

AT the annual meeting of the Detroit Architectural Club held at their rooms in the Union Trust Building on Monday, April 14, officers for the ensuing year were elected as follows: *President*, Cheri Mandelbaum; *Vice-President*, George H. Ropes; *Secretary*, Edward O. Schilling; *Treasurer*, John J. Fraunfelder; *Directors*, John Gillard, George V. Pottle and Adolph Eisen.

The reports of the officers and committees proved the Club to be in good condition.

At this meeting the criticism by F. B. Stratton on the Club's competition for a permanent band-stand at Belle Isle was announced, awarding to Louis W. Klei First Mention. On Tuesday following the meeting, the Entertainment Committee arranged for a theatre-party, after which a lunch was served at the Hotel Richter.

On Monday evening, April 23, a special meeting of the directory was called at which the committees that arrange the Club's work were elected: —

Class Committee: G. H. Ropes, *Chairman*, George V. Pottle and Edward A. Schilling.

Entertainment Committee: John G. Gillard, Fred Barnes and W. J. Ireland.

House Committee: John J. Fraunfelder, Adolph Eisen and John Mayer.

Publicity Committee: Adolph Eisen, *Chairman;* Louis W. Klei and Hans Geheke.

The Class Committee has arranged for a sketch-class in water-color during the summer months. The class will meet every Saturday afternoon.

All communications to the Secretary to be addressed to Edward A. Schilling, 48 Peninsular Bank Building, Detroit, Mich.

A. EISEN, *Chairman, Publicity Committee.*

COMMUNICATIONS

[*The editors cannot pay attention to demands of correspondents who forget to give their names and addresses as guaranty of good faith; nor do they hold themselves responsible for opinions expressed by their correspondents.*]

A CORRECTION.

SPRINGFIELD, MASS., May 7, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — In the last issue of the *American Architect* the alterations of three Colonial churches were credited to Messrs. E. C. & G. C. Gardner. As the work was executed before the firm of Gardner, Pyne & Gardner was dissolved the credit should have been given to the latter firm. Yours truly, E. C. & G. C. GARDNER.

NOTES & CLIPPINGS

PICTURE RESTORING UNDER NAPOLEON I. — "A Visit to Paris in 1814," by John Scott, Editor of *The Champion*, contains the following: M. Hacquin could not be content only to clean Titian's picture of Pietro Martire, but he must lay it on its face and plane away the board till he came to the actual color. He then put down pasted and glued canvas, that stuck to the color, and thus transferred the picture from wood to canvas. The members of the Institute were in an agitation of delight as this curious trick was in progress. "*Sacré Dieu!* What an undertaking!" An eye or a toe, a white cloud, a speck of color, on which much of the effect of this inestimable performance of the Venetian depended, was as nothing to the dexterity of the French remover. M. Hacquin was made a member of the Legion of Honor, and the whole body of artists and literati ran with wonder — not to study the picture of Titian . . . but to chatter, to shrug, to take snuff and to express admiration of the talents of M. Hacquin. The whole system of this cleansing and restoring is hateful. . . . An English artist told me that he was in the Louvre, studying the cartoon of the "School of Athens," when from a private door came forth an old Frenchman, who regularly set his palette and began to work on a large picture, the back of which was toward the Englishman. The latter thought it must be the performance of the person who was so busily employed on it, and from curiosity went over to examine it. To his horror he found the Frenchman engaged in regularly painting over an early and curious specimen of Italian art, touch by touch. He had painted the drapery of the Virgin entirely over, a fine staring blue. "Good God," said the startled Englishman, "who is this picture by?" "*Je ne sais pas, Monsieur,*" was the reply. "*Je ne suis pas peintre — Je suis Restorateur!*" It afterward turned out that this painting, so honored by the attention of *Monsieur le Restorateur*, was by Cimabue, and a most rare and singular relic. — *Notes and Queries.*

FACTS ABOUT LIGHTNING. — Many people admit, and more experience without admitting, fear of lightning. The feeling ranges all the way from vague uneasiness to frantic terror, and the aggregate amount of mental discomfort thus caused is very large. The *Electrical Review*, in noting the approach of the thunderstorm season, calls attention to the disproportion between the popular apprehension and the actual danger, but there is small consolation in that for the timid ones, all of whom know that the number of deaths from lightning is a negligible fraction in mortality reports, and still they are afraid. The *Review* disbelieves utterly in lightning-rods: at least it says that, "as usually put up, they are of practically no use." A tin roof, with metallic spouts connected with underground pipes, it credits with some protective power, but for the dweller in the country no close approximation to safety is attainable. The urbanite, on the contrary, is in no measurable peril, even if he takes no precautions at all, for, though city buildings are often struck, in hardly any instance does serious harm follow. It is well to avoid trees during thunderstorms, and stables containing animals and barns filled with new hay are also to be shunned. It is important to know that people are rarely killed outright by lightning. Many who die from its effects would recover if resort were had to artificial respiration, long continued. The production of lightning is thus explained: "When clouds are formed by the condensation of very minute drops of water from the vapor in the air, under certain conditions these drops exhibit a small electrical charge. As the drops coalesce the capacity increases less rapidly than the quantity of charge, for the reason that two drops of equal size, when they flow together, produce one of only slightly larger diameter, and the capacity is determined by the diameter. On this account the drops formed by the flowing together of the small mist particles, long before they attain such size as to be precipitated as rain, acquire an electrical charge of enormous voltage, sufficient often to leap a distance of a mile through the air."

THE STATUE CRAZE. — Boston just now is in the midst of a craze for statues, and the Legislature is flooded with bills making appropriations for them. Statues of ex-Governor Andrew, of Governor Wolcott, of John Hancock, of General Butler, besides a memorial monument to the Pilgrim Fathers at Provincetown as an offset to the monument on Plymouth Rock, upon which, say the Cape Codders, the Fathers did not first land, and other statues and monuments are called for from various sections of the State. Boston has always been well supplied with statues, such as they are, but of late its Art Commission has so impressed the municipal authorities with the badness of the statues that most of them have been kindly given to the suburban towns. This has left many sculptural vacancies, which it is now proposed to fill at the State's expense. The situation gives the Boston *Advertiser* the opportunity for a wholesome and sensible suggestion which might be heeded in many States besides Massachusetts. It says: "The State has no business to tax the people for monuments to dead men. Their relatives and friends should foot all the bills." And again: "The State might, perhaps, erect a monument to an idea, to a principle, but it has no business going into the mortuary-monument business when the dead man has friends who are perfectly able to meet all the expenses." Of course, if the suggestions were generally carried out, there would be fewer statues, but there would be compensation for this in the fact that there would be fewer bad statues. The good statues, like angels' visits, are few and far between. The bad statues are everywhere. Why should the State spend the money of the taxpayers to add to the number? for the statues secured by State appropriations are usually the bad ones. There is one exception to this general rule. In the case of a great national hero like Lincoln or Washington there could be no objection to Congressional appropriation for a statue, provided the conditions were such as to secure artistic work, but even in such a case a memorial set up by voluntary popular contribution would be preferable. But in the case of persons of State or purely local fame, if their friends wish statues erected as memorials of them they should foot the bills and not expect the whole people to contribute. Under any circumstances there is no danger of a statuary famine. What with individual gifts and bequests and collective contributions of societies, corporations and local communities, the supply of good, bad and indifferent statues will be kept up. There is no need for the State to add to the number. There is greater need for competent judges to examine the stock on hand and see how many are candidates for the dump or melting-pot. — *Chicago Tribune.*

VALENCAY. — Valençay is in the former Province of Berry, in the full centre of France, continuing the region frequented by all lovers of noble architecture for what are known as the Châteaux of the Loire. The château with its immediate dependencies — park and kitchen-garden, seed-plots, and pruning-grounds, and the largest of the eight forests — comprises over 7,000 acres, with an annual revenue, for the past twenty years, of some $14,000, of which $12,000 came in through the forest. Valençay was originally only the *seigneurie* of the Etampes family, belonging to the little nobility; but a marquisate came into the family, and there was an intermarriage with the Montmorencis, and so — three centuries ago — the owner tore down the old constructions, which were unfashionable in their Gothic rudeness, and built anew from plans of Philibert de l'Orme, who had just given the Tuileries to the critical Queen Catherine de Medicis. The château is built in a right angle, the other two sides of the square being completed by terraces of flowers and the orangery. The half-court of the traditional château, with its dark, damp corners where the two wings project from the main building, was thus avoided. The ancient moat surrounds the great building, and there is a donjon four stories high through which entrance is made from what was once the drawbridge. The exterior is sumptuous and majestic. The lofty windows and sculptured friezes were not surpassed during the French Renaissance, except at Chambord; if the latter is better known, it is because Valençay is off the line of tourist travel, and has never been open to visitors. Inside, besides the show-rooms and two libraries, there are twenty-five suites of rooms for the "masters," a chapel, and a vast number of separate rooms. The surrounding park, one of the most beautiful in France, covers 200 acres. The avenue leading up to the château is now the great high-road from the railway-station of Selles, and for a great distance its perspective is closed-in by the noble building, with its donjon and towers, and pointed roofs, with its cupolas and high decorative chimneys in the picturesque taste of the day. — *S. D. in the N. Y. Evening Post.*

A CONCRETE FACTORY-BUILDING. — A factory-building, five stories high and occupying a site of 50 feet by 25 feet has recently been completed in Jersey City, having the foundations, walls, floor-beams, girders, and roof made entirely of armored concrete. The building contains about 500 yards of Portland-cement concrete, and 12 tons of twisted steel rods, varying from ½ inch to 1 inch square. The ground-floor is supported about 5 feet above ground-level on foundation-walls with expanded bases of sufficient area to reduce the pressure on the unstable soil to 2,000 pounds per square foot. All the floors are designed for loads of 250 pounds per square foot, and each consists of a continuous concrete slab, 4 inches thick in the case of the ground-floor, and 2½ inches thick in all other floors, finished with a ½-inch granolithic surface. The floor-joists on the ground-floor are of steel-concrete, 26 inches from centre to centre, and measure 4 inches wide by 20 inches deep. They are flush with and supported by beams of similar material and depth, but 6 inches wide, each made in two lengths, so as to provide for expansion. On the upper floors the joists and beams are of lighter construction, and flanges are moulded on the lower edges of the joists to carry wooden beams, to which hangers for shafting may readily be secured. Twisted steel rods are carried through all concrete work, and the lower portions of the joists and beams are strongly reinforced in this manner for withstanding tensile stress. The steel rods are joined together by means of sleeve-nuts, and so continuity of support is secured. This factory-building is interesting as an example of concrete construction, but the adoption of concrete joists and beams seems to offer little advantage, while the great depth of such members would frequently be a distinct drawback. — *The Builder.*

A REVIVAL OF STREET-SIGNS FOR THE CORONATION. — There will be at least one symbol in Lombard Street worthy of the best traditions of the financial centre of the British Empire. This is the sign of the golden grasshopper from the family crest of Sir Thomas Gresham. He was an Elizabethan goldsmith, dealing in plate, jewels, coins and lace; and until he was knighted he lived over his shop in Lombard Street. He was a banker and a money-lender, and he charged percentages which would excite the envy of modern pawnbrokers. He had correspondents on the Continent, to whom he commended English travellers with letters of credit; and he exchanged foreign coin and melted down bullion for recoinage. He was an eminent financier, who enjoyed the confidence of the Ministers of Mary and Elizabeth; reduced the enormous charges of the bankers of Bruges and Antwerp in financing royal loans by inducing Londoners to take them themselves; built the first Royal Exchange at his own cost as a meeting-place for merchants, and converted London into the commercial centre of Europe. The first London bourse displayed at every corner pinnacle the golden grasshopper of Gresham, and it had classical and mercantile associations, for it was the favorite ornament of the Athenians in their best days, and was identified with the earliest enterprises of Phœnician commerce. There can be no more historic symbol of the worldwide activities of the financial resources of modern Lombard Street. — *I. N. F. in the N. Y. Tribune.*

NOTES AND CLIPPINGS. 56

COLUMBIA UNIVERSITY is taking an important step in separating its Schools of Architecture and Music from the departments to which they have hitherto been attached, and combining them into a new Department of Fine-Arts, to which will be added, later, if the proposed scheme is carried out, schools of painting and sculpture. Although the difference between a school of architecture as a branch of engineering and as a part of a Department of Fine-Arts is, perhaps, one of name merely, there is a certain importance in the definite ranking of architecture as a fine-art, and its students as artists. So far as we know, such a classification has never been made before in this country, and the following of the Paris precedent at Columbia will attract attention from the profession generally. All architects realize that too little attention is paid here, as a rule, to the æsthetic development of students of architecture, owing, no doubt, to a rather Philistine fear of making them "unpractical"; but it does not at all follow that a man who has learned to use architecture as a means of expression is any less likely to make skilful use of his materials; and, in the offices, a thorough comprehension of the qualities of brick, stone and wood is very likely to be found united with cleverness and originality in design. If Columbia University were one of the pretentious little institutions of learning which make their existence known to the public chiefly through the eccentricities of their officers, we should expect to see the classification of its students of architecture as artists signalized more by an abnormal development of whiskers and Rembrandt hats than by conspicuous advance in power of design; but the infantile period of its existence is long past, and neither shaggy curls nor pointed beards will do duty in its class-rooms in place of the hard work by which alone artistic excellence, as well as excellence of all other kinds, is to be attained.

THE Massachusetts Institute of Technology, in part through the liberality of one of its graduates, has acquired a tract of about twelve acres of land in Brookline, a few miles from the location of its present buildings. It is well known that President Pritchett earnestly desires for the Institute a more intimate social life, and freer interchange of thought, than has hitherto been possible, and it is quite likely that the purchase of land in Brookline may be a step in the direction of such a change in Institute affairs as may conduce to the wished-for end. Every one acquainted with the higher institutions knows that universities situated in the middle of great cities have much less of the college life than those more remote, for the obvious reason that a considerable portion of their pupils either live at home or have relatives in the city, and have thus a social circle of their own, entirely unconnected with their college; and the indifference of these to the social life of the college chills all the others. The University of Pennsylvania was, we think, the first of our great universities to provide for counteracting, in some degree, the social attractions of the city of Philadelphia, by establishing an admirable university club-house, where students could meet frequently, find congenial acquaintances, and interest themselves in the affairs of the college; and Harvard University, which, when it was founded, stood in an isolated village, accessible from Boston only by a ferry-boat, or by a circuitous path of many miles in length, has also found it expedient, now that the great city has been brought within a half-hour's ride, to counterbalance, by its beautiful Union, the increasing outside attractions. The Institute of Technology, having been placed, from the first, in the very middle of Boston, and provided with nothing but lecture-rooms and laboratories, has always drawn a very large portion of its students from families residing either in the city or its suburbs, while the others, as the Institute has never possessed anything like a dormitory, have been, necessarily, scattered among private boarding-houses all over the metropolitan district. This system, although unavoidable, has always been objectionable for other reasons, besides its total incompatibility with anything like social university life, and President Pritchett, although he is by no means the first of the Institute officials to appreciate the necessity for a change, deserves the credit of having been the first to break boldly with the tradition that the Institute could only exist in the middle of a great manufacturing city, and to declare that personal acquaintance, interchange of ideas, and the stimulus of sympathy and appreciation, are more important to a great institution of learning than simple proximity to manufacturing establishments. As a matter of fact, the industries with which the Institute is concerned are now scattered all over the world, so that any situation near enough to Boston to obtain supplies with facility would be suitable; while the applied science to which it is principally devoted has almost everything to gain by improved opportunities for discussion and collaboration among students of congenial tastes, and between these and their professors, such as would be afforded by giving the Institute more of the university character.

IT will be said at once that, while all this may be true for the engineering or chemical or biological departments, it does not apply to the architectural department of the Institute, which must necessarily be situated in the middle of a great city. This view of the requirements of an architectural school has prevailed in the Institute for many years, but the reasons usually given for it reduce themselves, on analysis, to two. One of these is that students of architecture should have always before their eyes the examples of the art which can be found nowhere else than in cities; and the other is that the Paris School of Fine-Arts is in the middle of Paris, and that, therefore, all other schools of fine-art, particularly of the art of architecture, should imitate the Paris school so far as they can. That there is something in the first argument cannot be denied. Students of architecture cannot learn their art from books and photographs, without plenty of study of actual work; and a city gives the best opportunity for such study; but the casual observation that a student, preoccupied with his work, gives to the buildings lining the streets through which he hurries to his lectures is of very little value in comparison with the deliberate study, made, if possible, under the direction of an instructor, and with sketch-book in hand, of proportion of stories, projection and profile of cornices and string-courses, modelling of carved ornament, and so on; and a student who lives a few miles from the town can have nearly as much of such study as one who lives within the city limits, while the former, if he can, after he gets back to his room, compare his sketch-book with those of a dozen of his friends, and discuss with them the refined beauties of a good piece of work, has a great advantage over a man who, as soon as his sketch is finished, must hurry off to keep some engagement at home, where, even if it should occur to him to take a second look at his sketch-book, he would have to content himself with his own thoughts in regard to it.

SO far as the Paris School of Fine-Arts is concerned, the main element in the beneficial influence which it exerts upon the whole artistic world is to be found in the sympathy and enthusiasm which prevail among its members, and which President Prichett is endeavoring to develop in the Institute. It must be remembered that, although the School is situated in the middle of a great city, its pupils come from all parts of France, and, indeed, of the world, and comparatively few of them have any social ties in Paris. Moreover, every student in the School must belong to an atelier, and the rivalry between the ateliers in the pursuit of prizes excites not only an interest among the students in each, but an earnestness in criticising and assisting each other, which are of incalculable

Entered at the Post-Office at Boston as second-class matter

value. Nothing like this has ever existed at the Institute. Although it has often been proposed by Paris-trained Boston architects to introduce a modified atelier system in connection with the Institute, the plan has never been found practicable. With a more intimate student life, while there would be no atelier rivalries, there might be, and probably would be, with the sensitive and enthusiastic American temperament, a great deal of the friendly criticism and encouragement of the Paris ateliers; while the extension of the mutual relation between American universities, which has been found so valuable, is likely, before long, to give opportunity for a most wholesome and stimulating emulation among students of architecture.

MR. EDWARD ATKINSON makes an earnest appeal to all persons interested in the subject of saving to the community the enormous losses which it suffers from fire to make a contribution toward the comparatively insignificant sum of one hundred and fifty thousand dollars, with which either a separate school, or, what would be much better, a Department of the Massachusetts Institute of Technology, can be equipped and endowed for the purpose of teaching the science of preventing or checking fires. Mr. Atkinson calls this science Insurance Engineering, and if all officers of insurance companies were like him, the name would be an attractive one to the public; but, we are sorry to say, so many people, at least in this country, have suffered from the impudence and dishonesty of irresponsible insurance agents, and from unreliable, not to say swindling, insurance companies, that it will be a long time before the community in general is likely to look with favor on any enterprise which has the name of insurance attached to it. If, however, we can call the new school an institution for the study of the art of fire-protection, it should commend itself to every one. The people of the country are rapidly learning that the money which they spend every year in unnecessary fires would keep them all supplied with boots and shoes, or, as Mr. Atkinson puts it, would more than pay all the expense of conducting the Government of the United States, apart from pensions and the interest on the public debt; while, as he points out, every large fire in a manufactory, or a great mercantile house, throws out of employment, and, in most cases, keeps out of employment, until the establishment can be rebuilt, a multitude of persons, whose loss in wages is not made up to them by the insurance companies, and does not figure in the statistics. The prevention of fires has come, therefore, to have a personal interest to a very large number of people, apart from those who regard it simply as the most important of modern economic problems, and a well-considered scheme for the scientific study of the subject should find, and is likely to find, ample support. As Mr. Atkinson says, the necessity for something of the kind is every day becoming more urgent. While manufacturers, through their admirable mutual companies, are able to protect themselves, merchants who carry large stocks of goods find increasing difficulty in obtaining adequate insurance on any terms, at the same time that costly buildings are being erected on all sides by a system of construction which has never yet been thoroughly tested, and the study of the durability of which could with great advantage occupy the attention of experts.

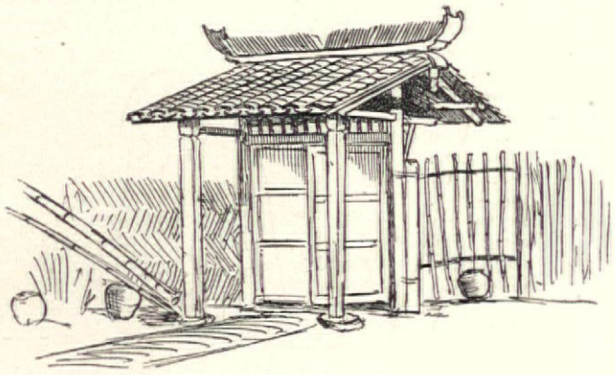
HOW imperative is the necessity for responsible and authoritative investigation of these points is well illustrated by two documents which have, probably, been placed in the hands of most architects within the last two weeks. The first, published as an extract from an address delivered before a body of experts, declared the modern steel-frame construction to be unreliable, quoted instances where steel columns, buried in concrete, when stripped of their covering some twelve years after they were set in place, had been found rusted half through, and warned those interested that no covering of concrete could prolong for many years the life of a steel frame. In a few days this document was followed by another one, also a reprint of an address delivered before a company of experts by a scientific man of distinction, in which it was boldly asserted that, while "opportunity to determine the condition of steel imbedded in concrete after years of exposure to air and moisture is seldom obtained, . . . in all cases in which such work has been taken up and examined the metal has been found bright and free from corrosion." This assertion is supplemented by another, that "even though the concrete be porous, and not in contact with the metal at all points, it will still filter out and neutralize the acid, and prevent its corrosive effect"; the acid being the carbonic acid of the atmosphere, to which, as the author of the address says, the rusting of iron is due. It may be imagined that architects, supplied with contradictory information by experts in whom they have reason to place confidence, find it difficult to ascertain the truth. To them, as to their clients, it is of great importance to know whether steel construction, surrounded with concrete put in with ordinary care, is reasonably permanent, and the opposing views of experts not only confuse them, but injure their influence with their clients, who can always find in technical literature something to contradict the architect's opinion, whatever that may be. With such a school as Mr. Atkinson proposes, this difficulty, which is a very serious one, as all architects know, will disappear, the determinations of its members superseding the *ex parte* deliverances of amiable or prejudiced engineers as completely as, for example, Professor Lanza's determinations of resistance of timber have superseded the assumed constants of twenty years ago.

IT is definitely decided that the Louisiana Purchase Exposition, or, as it is generally called, the St. Louis Fair, will be postponed until 1904. It has long been evident that the opening of the Exhibition next May was impracticable, and the public, as well as the exhibitors, will breathe more freely at the announcement of the postponement. Experience has shown that nothing is more detrimental to the success of such an affair than failure to have it ready on the opening day. Even at Paris, in 1900, the attendance during the beautiful weather which prevailed for a month after the opening of the Exposition was far less than it should have been, owing to the widespread impression that it was not ready. It is true that, on the opening day, and for some time afterwards, many of the exhibits had not been unpacked, but there were plenty of other things to see, and it was a misfortune for the public, as well as for the Exposition, that multitudes of people, in order to be sure that everything should be ready for inspection, put off their visit until the intensely hot weather of June and July made sight-seeing painful, if not impracticable. If the managers of the St. Louis Exposition are wise, they will take advantage of their extra year of time to insist that everything that is to be shown shall be in place, ready for visitors, on the opening day, and that nothing shall be received afterwards. If it is generally known that those who come to the Fair on the opening day will see everything that can be seen by those who come a month later, sensible people will arrange to make their visits as early in the season as possible, and the Exposition will not only have a successful start, which is of great importance, but will be the richer by the entrance-fees of many thousands of people who, if they waited until the scorching days of a St. Louis July before coming, would never come at all.

MR. DANIEL WOOD writes to the *Builder* some interesting observations, which are, however, not wholly new, on the ancient method of drawing the volute of the Greek Ionic capital. It happened to him, some twenty years ago, to be engaged in making a reduced copy of the temple of Nikè Apteros in Athens. In laying out the volute of the capitals, after trying, with the usual result, to draw the curve by Goldman's method, it occurred to him that a pencil, fastened to the end of a string, which was wound around a cone, would draw a spiral, similar to that of the volute, easily and smoothly. He tried the experiment, using a cone with a point, which was set in a hole in the drawing-board, and found that he could draw a very successful volute in this way. As the end of the cone which entered the hole in the drawing-board was of a certain size, he found that the inner revolution of the spiral could not be drawn with the string, and he improved upon his method by placing the cone with the point up, which answered perfectly. On applying his method to copying the volutes of actual capitals preserved in the British Museum, he was surprised to find that a hole existed in the "eye" of each volute in the marble originals of other Greek Ionic capitals, large enough to admit the cone which he proposed to use, with the point up; while, in the capital of Nikè Apteros, the hole was so small that the cone had to be placed with the point down. In either case, however, a pencil and string, unwinding from a cone of a size to fit the hole, described exactly the spiral cut on the marble. In the case of the Erechtheum capital, and some very early examples, there is no hole in the eye of the volute, but it does not follow that a cone may not have been used for drawing the curve, either by holding it against the stone, or by setting it in a shallow hole in the rough block, which was cut away and smoothed over in the finishing.

JOURNAL SKETCHES IN CHINA.[1]—III.

IN the evening we all went to the theatre in the Chinese quarter, outside the city walls. The Chinese theatre in San Francisco gives one a fair idea of the native one in Shanghai, but for rich colors and gorgeous effects of dress and banners, bizarre painting of the



Gateway: Farmhouse near Shanghai.

face and ear-piercing sounds I have seen and heard nothing to compare. I did not tear myself away till midnight and could have remained much longer. The audience-hall was large and spacious, though barny. The floor was covered with small square tables, at which parties of four sat in hard-bottomed chairs. These tables were scattered in an irregular way all over the room. There must have been at least a thousand men on the floor, with not a woman to be seen among them, and I was apparently the only foreigner present. The galleries and floor were packed with an orderly set of people, all talking and apparently paying but little attention to the play. In the gallery, near the stage, were large boxes in front of which were green baize curtains to be lowered in case they were occupied by women of the higher class; now they were crowded with women of the common class, every one with her hair properly arranged in the peculiar and picturesque style of Chinese hair-dressing. Certain portions of the play were shockingly indecent and excited much laughter, yet no one looked to the galleries to see if the women minded it, nor did I see the slightest evidences of disapproval. After we had taken our seats a boy came along bearing a large tray containing dishes of watermelon seed, *li-chi*, fried peanuts, oranges and a weak rice soup. Another boy soon followed bearing in his hand a pile of square pieces of thick quilted cloth; these were wet and steaming hot. Each one took a piece and wiped his face and hands. These had already been in use before being offered to us. I naturally declined to use a cloth that had already mopped the dirty mouths and faces of a number of Chinese and was probably looked upon as extremely fastidious. It is in matters of this nature that the uncleanliness of the Chinese must be insisted upon. My companion told me that the Chinese always used hot water, and not cool, for their faces, and that in the city there were stands where the poorer people could buy hot water for a trifling sum for the making of tea and for other purposes. Still another boy came to our table bearing a tobacco-pipe and a light, and this circulated among the audience. It was often smoked, yet I saw no one wipe the mouth-piece before using. No wonder infectious diseases have full sway among these people. Those who had their own pipes had a slow-match consisting of a roll of paper as big as a candle, and this could be blown into a flame when occasion required.

It was curious to observe the absence of concentrated attention that one sees in our theatres, and, indeed, as a play will occupy some days and even weeks in its presentation, it would be beyond human endurance to sustain the strain of attention. My companions apparently understood but little of what was uttered by the actors and it seemed impossible that the audience did, judging from their lack of attention. It was explained to me that there were long monologues and recitatives of no special interest, the familiarity of the audience consisting in a knowledge of the general plot, or story, and not with the words uttered.

When it is realized that there are many languages and hundreds of dialects in China, a troupe foreign to the immediate locality would be speaking in a tongue unintelligible to its auditors. If the text in Chinese characters could be flashed upon a screen as the play progressed, then from one end of the Empire to the other a fair idea of what was being said could be gathered, by all the scholars, at least.

In the acting there were the same absurd conventionalities that one sees on the Japanese stage. For example, the hero is supposed to ride away on horseback; to represent this equestrian feat he waves his hand in the air, flings his legs over an imaginary horse and then prances — but not off the stage. As in Japan, the woman's part is taken by a man. To get the appearance of the compressed foot of the woman the whole foot is rigidly bound with bands and a small shoe is provided which fits the toes, the actor literally moving about on the tips of the toes, at the same time squeaking in a high falsetto voice. The impersonation is wonderful.

. . . . . .

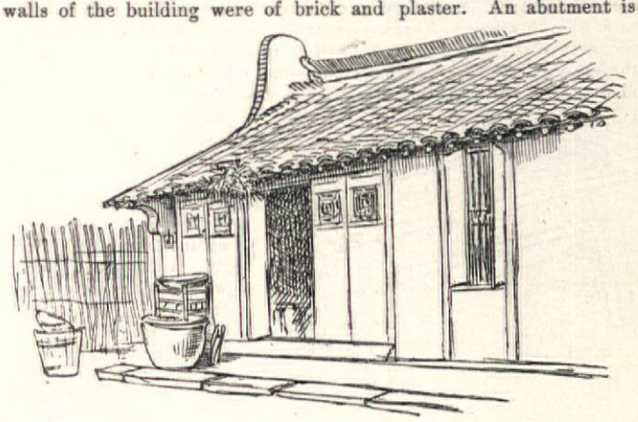
I saw a disgusting sight from the banks of a narrow canal near Shanghai. In the canal were low open barges, like canal-boats, which had been poled or towed down from the interior. These were the receptacles for the sewage of the city, and carriers were coming like a string of ants, bearing buckets of this material, which they had collected in the city from house to house. These were emptied with a splash into the barges, in every case some of the stuff spattering into the river. The canal itself was green and yellow with filth, and yet women were along the banks washing rice, and some were dipping up water in buckets and carrying it away, possibly to water their gardens, and one could not imagine a more generous fertilizer.

Thus far I had seen the interior of three houses of the more favored classes; they were all essentially alike in the high walls, courtyards, rooms and dirt, and I was told that one house would answer as a type for the thousands in Shanghai.

The next day I had an opportunity of walking into the country with Mr. Drew, who was to visit an old nurse of the family. This woman owned a little house on the side of a muddy creek. Whether the house had belonged to a richer person before coming into her possession I did not learn; it was interesting, however, to observe the conspicuous gateway to the yard. The prominent gateway is a distinguishing feature in the Orient. The evidence of taste and time bestowed on the main entrance is not only seen in Japan, but in Anam, the Malay Peninsula, and Java, though in Java there are so many Chinese that this feature may be due to Chinese influence. In our country and in Europe the estates of the wealthy are marked by prominent and conspicuous gateways, while among the masses this is rarely made a prominent feature.

The fence on one side was a ramshackle affair of split bamboo in braided patterns; on the other side simply bamboo poles. The framework of the gateway showed some little carving; the superstructure was heavily tiled and the ridge had tiles placed vertically, as in the roof-ridges already described. The gateway and fence were in the usual dilapidated condition. The house or houses formed three sides of a quadrangle, the fence and gateway bordering the road making the fourth side, the space thus enclosed making a rather spacious yard, which was wet and muddy. There were no evidences of an attempt at a garden, and the yard and surroundings presented a most forlorn appearance. The houses were one story in height, and the roofs were all heavily tiled. The walls of the main house which faced the gateway were wattled and plastered, though this was broken away in spots, exposing the bamboo wattle beneath. The main entrance to the house was recessed, and on the right and left sides of this recess were the doorways, and on each side of the entrance was a window closed by two outside wooden shutters. Wooden hooks were suspended by cords from the overhanging eaves, and on these hooks hung the peculiar Chinese shoe to dry, an indication that the felted sole of the Chinese shoe absorbs water. A mass of straw and twigs was piled up on the side of the house, this material representing the wood-pile. Charcoal is also used as in Japan, but not by the poorer people. For fuel, dead leaves, bits of straw and twigs are garnered along the roadside. The cast-iron kettles are made with the thinnest possible bottoms, in order to utilize every particle of heat emitted from the burning of this light material. In our great country, with its long streaks of Oriental blindness and stupidity in not enacting and enforcing proper laws for the preservations of the forest, it will not be many generations before able-bodied Americans will be seen picking up dead leaves and dried pods along the road in order to cook their dinners.

The accompanying figure presents a view of another building of this group running at right angles to the main house, its end abutting on the road. In this portion was a bedchamber and also a large room for the making of homespun cloth. The little wooden framework resting on top of a big water-jar, and in its turn supporting a shallow pan which had been dropped there, represents a sort of cage in which the baby is confined when sitting on the ground. The walls of the building were of brick and plaster. An abutment is

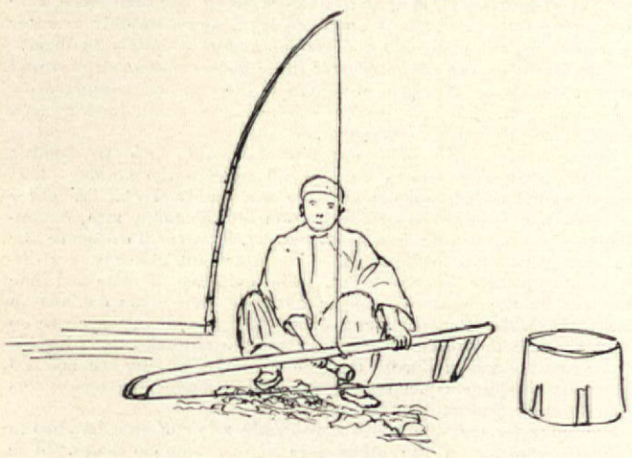


Farmhouse near Shanghai.

seen at the end of the house next the fence, and in this abutment was a little square niche with an ornament of flowers made in stucco. Over the doorway was a bundle of green shrubbery, evidently placed there to commemorate some event. The window, like the others, was closed with heavy wooden shutters. Besides the large window were a few small openings with close framework covered with paper.

[1] Continued from No. 1376, page 46.

Within was a large barn-like room with dirt floor and roof-rafters showing, in which were all the devices for converting raw cotton into cloth — a primitive cotton-factory. These simple and home-made devices were so interesting that I sketched them all. The cotton-gin consisted of two wooden rollers moved by a treadle which was connected with what answered to a balance-wheel in the shape of a heavy stick of wood larger at the two ends; the slender roller was

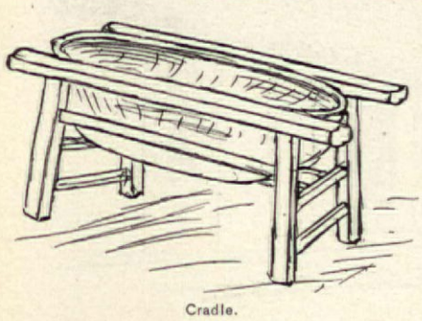


Device for cleaning Cotton.

of iron; all the other portions were of wood held together by wooden pins. The little hand-crank at one end was simply to start the machine. The device for making the raw cotton fluffy and shaking out the dirt seemed to be a very efficient machine; it consisted of a heavy wooden piece, 7 feet in length, abruptly curved at one end; a stout cord was strung to this as in a bow, a bridge at one end enabling the cord to be made tense. In appearance it reminded one of a colossal bass-viol bow. This was held from the ground by a cord which was fastened to the end of a long bamboo, rising upright from the ground, but now bent from the weight of the bow. To operate this, the person sits on the ground; before him is a pile of dirty and compacted cotton; in the left hand he holds the bow; in the right a thick knobbed stick; with this he violently twangs the cord, which vibrates rapidly in the pile of cotton in a most effective manner. The cotton by this process is quickly reduced to a fluffy condition and is now ready for the spinning-wheel, which was a primitive and rickety affair. The wheel was turned by the foot resting on the bar, the woman sitting on the bench at her work. Three spindles came out just above the wheel and three threads were spun at a time. The loom was equally rude and the old woman who was weaving when we entered the room was working with the same tireless energy that seems to characterize these people in all their vocations. The old nurse was very polite and kind and seemed greatly interested in showing and explaining everything.

The figure here given shows the baby's cradle, consisting of a thick basket held in a stout framework of wood. The mother removed the sleeping baby and placed it in what looked like an old-fashioned milk-churn, but was in reality a baby's high-chair. A floor-like partition within prevented the baby from going to the bottom. The inside of this churn-like receptacle was highly polished by the successive generations of babies who had wriggled in it.

During all my sketching in the house I was surrounded by fifteen or twenty men, women, and children who had drifted in from the neighborhood. The crowd seemed to be quite as inquisitive as a Japanese crowd under similar circumstances, but far less gentle and polite. In this house I was permited to see a woman's bedroom. The room was small and dark and it was difficult to get enough light, even with the door open, to make out clearly the various objects and details. The appointments were not unlike those in our own chambers; a dressing-table littered with the usual clutter of a disorderly bedroom; a bureau holding three drawers rested against the wall. On the top was a tall wooden candlestick, a few small jars and other objects. On the wall behind was a hanging scroll with the picture of some god or household deity done in black and white. Chairs, low stools, and a table, with no semblance of order, were about the room. In one corner was a large finely carved bedstead with heavy frame above to support the bed-curtains. The rafters of the room were exposed above. At one side was an attic or space under the roof, the floor of which formed the ceiling of an adjoining room. I noticed, as with us, the same accumulation of attic rubbish, too useful to throw away and too worthless to keep, stuff upon which more distracting brain energy has been wasted by man than in the writing of big books.



Cradle.

. . . . . .

The few temples I saw in Shanghai left the impression of neglect. They were certainly dirty, as were the priests connected with them. It was hard to trace the same cult after seeing the Japanese Buddhist temples. In one temple which I visited there was a room, more like a shop and suggesting a dime museum, opening directly off the street, in which were various effigies arranged in order on a series of step-like shelves. A few people were engaged in prayer. In the midst of these devotions a woman came in and scolded in a high, strident voice. No one interfered or apparently noticed her actions. My escort thought she was insane.

Baby Chair.

. . . . . .

As I left the city at twilight after my brief experience within its walls and glanced back through the gateway to take a last look at its narrow streets and low buildings and, recalling the mass of filth, misery and small-pox, I noticed a Jesuit priest with heavy black beard and unmistakable French face, but dressed in full Chinese costume. He was entering the city, in which he lived surrounded by all the squalor and misery. I could not help admiring his noble devotion and could readily understand why the Catholics make such progress in China in comparison with that made by the missionaries of other sects, who usually live in the foreign settlement, associated with many of the comforts of their more sinful brethren. I further realized that a convert of this priest might compare notes with a Catholic convert in Thibet or Cochin China and there would be no divergence of doctrines in the minutest particular.

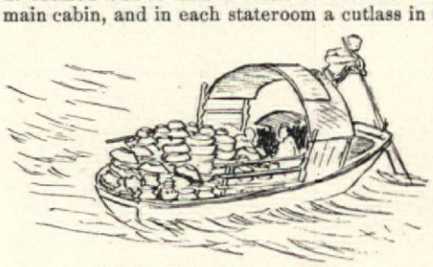
. . . . . .

After a hasty good-bye to my American friends, who had been so kind to me, I started for Hong Kong in an English steamer, having a quiet, uneventful voyage, good substantial food, exceedingly pleasant travelling-companions, and whist most of the time.

In sailing up the passage to Hong Kong an expanse of rocks loomed up which had I seen on the Norway or Maine coasts I would have insisted they showed typical glacial erosion.

From the damp, cold and shivering weather of Shanghai we had been transported in three days to a tropical climate. In the parks and gardens were palms, big ferns and a most luxuriant vegetation. The city is policed by Sepoys and on the streets one meets many races: heavily turbaned Hindoos; Parsees, with their caste-marks on their foreheads, which, curiously enough, seemed perfectly natural; Malay and Indo-Chinese, and red-coated British soldiers. The greater mass of the people were, of course, Chinese, who, alone of all the various peoples, showed the same interest and persistent activity that I had observed in Shanghai. There were slight differences in the dressing of the women's hair, but the clothing appeared the same, and the narrow streets of the Chinese quarter, though cleaner on account of English domination, sent out the same unsavory odors.

A day only in Hong Kong, and late in the afternoon I left the city on a steamer bound for Canton, a regular white, side-wheel steamer of the American type, with a Salem commander, Captain Lefavour. It seemed odd to find a stack of cutlasses and loaded guns in the main cabin, and in each stateroom a cutlass in a rack near the berth. On inquiry as to the necessity of these war-like preparations I was told that only a few years before the steamer "*Swift*" on the same route had been captured by pirates, and all the foreigners, but one, on board murdered. As pirates still abound on the river, these precautions are wisely considered necessary.



Pottery Pedler on Canton River.

It began raining at dark, and continued to rain throughout the night. The darkness was impenetrable, and it seemed incredible that any one could navigate a boat in a tortuous river under such conditions. We reached Canton the next morning at nine o'clock, the boat having anchored during the night on account of the storm.

A wonderful sight presents itself as you near the wharf. The river in places, and over large areas, fairly swarms with covered boats, literally thousands of them of all sizes and conditions, and these boats

represent the dwelling-places of families, who for generations have been born, have lived and have died without knowing any other living-place. All the trades and manufactures of a great city are represented in this agglomeration; fruit-boats, peddlers' boats of all kinds and the famous flower-boats, or, more properly, gaudy boats, a rendezvous for harlots.

The preceding figure is a sketch of a pottery peddler, who, with his stock-in-trade of pots and jars, pans and flowerpots, piled to the gunwales, plied his trade up and down the river and in and out of this maze of floating craft.

One could not help wondering at the distractions of a census-taker were he assigned to enumerate the river population. The conveniences of such a residence were immediately apparent when it was realized that one could easily sweep overboard all the dirt and dispose of all the garbage; there would be no sewage nuisance unless the river might be considered a sewer, and in either case the Chinese are apparently immuned physically — absolutely so mentally — and filth and stink give them no annoyance; no lawns to mow or sprinkle; no wells running dry or water to shut off, and when a child disappears no harrowing suspense for days, but quick realization of the calamity, if calamity it appears to these cultivated savages; no upstairs nor downstairs; no cellar to clear up nor attic to put in order.

The boat is not only a residence, but a passenger-conveyance, a baggage-wagon, a peddler's cart, a blacksmith-shop, a bakery, indeed it lends itself to every demand of life, active or idle. A glimpse into some of the boats showed them to be fairly clean and prettily fitted up in the way of pictures, bright-colored curtains and tinsel. The larger boats had lashed to their sides blocks of wood in which were square holes for the convenience of boatmen who have to ward them off or push along their own boat. As to the model of these boats, for they all seemed alike save in size, a watermelon cut lengthwise would give a very good idea of their shape. They were apparently cranky, but evidently dry. EDWARD S. MORSE.

[To be continued.]

STRUCTURAL COLOR-DECORATION OF THE INTERIOR OF PUBLIC BUILDINGS.[1] — III.

DISCUSSION.

THE CHAIRMAN said that Mr. Horsley had given them a very comprehensive sketch of a very large subject. It certainly seemed to him (the Chairman) as if English people had almost ceased to regard art as of very much public importance, or as an important means for the expression of national thought and aspiration, to say nothing of history and the idealizing of daily life. In that sense Mr. Horsley made an interesting point when he spoke of the decline of fresco-painting and the decoration of churches and public buildings, upon the incoming and popularization of literature and printing, and the multiplication of books. He (the Chairman) was strongly of opinion that the painted walls of the public halls and churches in the Middle Ages acted in a great measure as public libraries, or were a sort of equivalent for them, through presenting before the public the great facts of religious and national history, symbol and legend. He regretted that Mr. Horsley had not been able to secure specimens of the very interesting series of wall-decorations by Madox Brown at the Manchester Town-hall. Most of the illustrations which they had seen were of French origin, or showed French influence, but the designs of Madox Brown were characteristically English, and showed remarkable dramatic sense and vivid power of conception, with a certain naturalism and local truth of detail, giving one the sense that the artist had been an actual spectator of the historic scenes he depicted. He entirely agreed with Mr. Horsley in thinking that there was an immense advantage in working upon the painting *in situ* and painting in the light in which the work was to be seen: but there was also a great practical disadvantage because the work was generally built-in by scaffolding, and the artist was never really able to get away and take a fair view of it before the scaffolding was removed. Barring that disadvantage, there would, perhaps, be better results if mural decorations were painted *in situ*. It was related that Mr. Watts made an offer to the London and North-Western Railway to paint the walls of the great hall of Euston Station if the Company would be answerable for the cost of the materials, and that the offer was declined. That was, perhaps, an indication of the way in which public art was regarded. At any rate, it would appear the Company did not wish to detain people in the hall of the station, but wished to hurry them forward to take their tickets for their destination. Perhaps many of them might have missed their trains if the painting had been carried out. He was quite in accord with Mr. Horsley with regard to *tempera*. He thought that *tempera* was a medium presenting few, if any, technical difficulties, and having very great resources and advantages, including the advantage of durability. He did not think that Mr. Horsley had said very much about tile-decoration generally. Possibly that might be regarded more as an external decoration, but he had often thought that more might be done in the way of glazed or terra-cotta relief, in the method of the Della Robbia ware, as decoration. Certainly, such bold effects of color and brilliant white associated with that material were, perhaps, more suitable in the open air and in inner courts and places where reflected light was required, and, even there, associated with mural and architectural design of a particularly light-toned character. As a rule, when it was applied in this country it seemed to be in glaring contrast to the color of the materials of the building.

SIR THOMAS WARDLE said that, as a member of the Applied Art Committee, he had advocated the proposal that a paper should be read on the decoration of the interiors of public buildings, and he associated with the subject the name of his friend Mr. Horsley, of whose work he had had some experience in North Staffordshire. They there had some of Mr. Horsley's work as an architect, and it was no small pleasure to find that when Mr. Horsley suggested color-decoration for his church-architecture there, he had given them a series of paintings without which the churches in which he had worked would be bare indeed. He remembered going on several occasions to speak to him during his work at All Saints' Church in Leek, and he found him generally lying on some planks in the top of the chancel, almost invisible, but completely devoted to his work. The results of that work were very pleasing and excellent. This subject had been introduced to remove the prejudices of people. Many people in the land seemed to prefer a plain building to a decorated one. When he (Sir Thomas Wardle) advocated the subject, he did so more with regard to places of worship, as to which he had spoken in two or three papers which he had read. He had often been very much pained, on going into churches and chapels, to see the utter absence of decorative work; the worshippers in such places feeling that the buildings were better without decoration. That feeling had perhaps descended from the old Puritan times, but he believed that it was passing away. He might instance a Nonconformist chapel in Ashton-under-Lyne, where there was one of the very best windows by Sir Edward Burne-Jones and William Morris. The more that window was seen, the more it was appreciated. The same might be said of Scotland, where artistic influences are rapidly becoming general. He thought that good would be done by such a paper as Mr. Horsley had read. England was now paying much attention to art and color, and we might well rise superior to prejudice and avail ourselves of the skill which lay at our hands. In his town there was a rather amusing difficulty. Some years ago, his dear friend the late John Sedding designed a reredos for Saint Luke's Church. It was an admirable piece of work and consisted in part of sculpture. The design was a colored one, and the Puritan spirit of the town rose against the color. The people did not object to the figures or to the marble, but they objected to the figures being colored. He begged that the pictures should be painted in distemper that it might be seen how they looked; and no sooner had that been done than the whole congregation were pleased with the result. It had now become necessary to clean the reredos and repaint it, and it was to be repainted in colors as the architect designed it. Now, unfortunately, the old spirit had risen up again, and the parish was rent in twain, and some had objected to the painting being done. Papers like that which had just been read might be well directed against such weak and ignorant prejudices. They had only to look at the beautiful room in which they were assembled to see the value of decorative work. He was sure that the decorations in the Town-hall of Manchester, to which the Chairman had alluded, had had a great effect on the minds of the majority of the people in the district. At Cheadle, in North Staffordshire, there was a church built by Pugin the Elder, who decorated it from end to end. It was built about forty-five years ago, and it was one of the most beautifully decorated churches he had ever seen in his travels either in this country or on the Continent. He did not think that there was a square foot that was not decorated or painted.

MR. T. R. SPENCE said that all the materials that Mr. Horsley had advocated in his interesting paper were extremely good in their way. There was, however, the great question of design. There was a very glorious example of color-treatment in marble and tiles which Mr. Horsley did not mention. He referred to the Mosque of Omar in the temple area in Jerusalem. The whole of the outer walls of that building up to the eaves of the side-chapels were covered with a very beautiful arrangement of various colored marbles. The outer part of the wall which supported the dome was covered with most beautiful Arabesque tiles, and, of course, the effect of the marble and the tiles together in the beautiful Eastern light was beyond description. It seemed to him that in decoration in England we were too much afraid of color. His view was that the more effulgent the color was the finer was the result. He strongly advocated that the various tones of color should be rich and effulgent, and not limited to the pale grays and shabby greens which had been very much used in recent times.

MR. W. WOODWARD thanked Mr. Horsley for his very interesting and very valuable paper. He hoped that the paper would do some good in inculcating the idea that English artists were quite capable of successfully decorating English buildings. With regard to Mr. Butterfield's work at Oxford, he was sorry to differ from Mr. Horsley in his commendation of that work. He must confess that when, some quarter of a century ago, he visited Keble College, at Oxford, he thought that not only architecturally, but decoratively, Mr. Butterfield had imported into grand old Oxford something which was antagonistic to its associations. Two years ago he visited the place again, and he found that the effect of time, that grand adjunct of art, was evident in Mr. Butterfield's work. Time, as

[1] A paper by Gerald C. Horsley read before the Society of Arts, and published in the *Journal* of the Society. Continued from No. 1375, page 40.

they all knew, did an immense amount of good for all art, and particularly with regard to architecture. He had been very glad to hear Mr. Horsley speak of the mosaicwork in St. Paul's Cathedral. One had only to look first at Sir William Richmond's work and then carry one's eye to the work of Salviati in the dome to see how very much more effective was the work of Sir William Richmond than the work of Salviati. Mr. Horsley had referred to the importance of the architect and artist working together in sympathy. They would all agree in his view in regard to that point, but he was sorry to say that, in a recent work of his own in which he had expended very considerable care in detail, the decorative-artist acted upon his own initiative and produced a result which displeased him (Mr. Woodward) very much. But if the sentiment that Mr. Horsley had expressed was carried out, there could be no doubt whatever that our public buildings would be far better decorated, and far more presentable, than they were now. In speaking of mural decoration, Mr. Horsley had omitted to mention a work which appealed to every one who had seen it — Lord Leighton's lovely representation of the "Wise and Foolish Virgins," at Lyndhurst. That was, he believed, one of Leighton's earliest works. With regard to the materials, marble and mosaic, of course, had the advantage that they did not require restoration or re-doing, but he must confess, that marble and mosaic in London, unless they were kept perfectly clean, and had some attention paid to them, suffered considerably in the course of a very few months. A very fine effect was produced by simple cleanliness, and this was needed in external decorative work in London. There was another matter with regard to London decoration which Mr. Horsley had not mentioned, and that was the attempt made some years ago by Messrs. Novello in their music-establishment in Berners Street. It was an example of external decoration which looked exceedingly well, but it had suffered from the effects of the London atmosphere.

Mr. Phene Spiers said that the address was one of a most interesting kind, but it was certainly not in accordance with the title given of the subject. He had anticipated a paper on the necessity or advisability of accentuating the constructive features of buildings by color-decoration. That was a point which he hoped Mr. Horsley would take up on some future occasion, for it was of the very greatest importance. It had been brought to his mind this evening by two of the slides which had been shown of Colchester Town-hall, in which Mr. Belcher had been able to accentuate the constructional forms of the designs by the color-decoration which he had used. If an artist was brought in whose views were not in harmony with those of the architect who had not considered the buildings from the architect's point-of-view, and who failed to understand the constructional features, he would be quite liable to contradict the constructional forms by the decorations which he put in. Therefore he thought that the color-decorations of a building should be conceived from the first and that the work which the artist did eventually should be done with an understanding of the design of the architect. A totally wrong effect might be given by calling in an artist who did not understand the scheme of the architect's work. Referring to the opinions expressed as to the method of fixing mosaics, he was talking the other day with the artist who had designed the mosaics for the Albert Memorial, and who said that he was of opinion that if an artist was employed in putting the *tesseræ* down on the face of the drawing, the question of putting them up in their position and the waving of the various faces of the cubes could be easily managed, and he spoke very strongly in favor of that system of work, and alluded to an example in which superior results had been arrived at by adopting that method. He (Mr. Spiers) only mentioned that incident to show that there might possibly be two points-of-view.

Mr. C. Baskett said that as Colchester Town-hall had been alluded to, he might state that he was the person who decorated it, and he was pleased to say that the architect and he were working together in every way. When he (Mr. Baskett) took up the design, he tried to enter into the spirit of it. He considered it the duty of a decorator, when an architect was in charge, to try and enter into the spirit of his design. He had endeavored to do so with Mr. Belcher, and the result was harmony and success in work. Mr. Horsley had alluded to damp walls. Twenty-five years ago, he (Mr. Baskett) had had to decorate a church wall that was exceedingly damp. A few months after the work had been done, it had perished. In order to meet the difficulty, he had some lead rolled very thin, about three pounds to the foot, and cemented it upon the wall. The lead was painted and stippled, and it became a beautiful surface to work upon. He was at the church a few weeks ago, and the work was in as good a condition as at first, but the work which had been put on a wall close by, which was considered dry and safe, was altogether gone. It had struck him that the meeting might want to know how the difficulty was dealt with. After the lead had been applied to the wall with cement made with pitch, mixed with a little tallow, it was ironed with hot irons to ensure cohesion, and it had stood thoroughly well.

Mr. G. C. Horsley, replying, said he thought that they had had a very interesting discussion. It included points upon which naturally he was unable to touch in a paper such as that which he had read. The subject was a very large one, and opened up many avenues for consideration, and it had been impossible to touch upon more than a very few. What had been said by Mr. Spiers as to the necessity of the decorative designs of a building being in sympathy with the construction, and expressive of the construction, formed a valuable supplement to the paper. At the same time, that was a point which must depend very much upon the painter and his consultation with the architect; and he conveyed in his paper that if there was no proper sympathy between the architect and the painter, that is to say, a thorough knowledge of each other's work — in short, a knowledge of art — there could be no good decoration. It was a subject upon which all architects felt very much. He was very much obliged to Sir Thomas Wardle for what he had said about prejudice against employing artists in decorating buildings. If people had a little more confidence in artists and a little more desire to see what they could do, they would be better pleased. The prejudice against artists was a thing which they must try to overcome; the public must be educated as to that matter. Sir Thomas Wardle had spoken of the effect of the fine paintings of Madox Brown in Manchester. He (Mr. Horsley) regretted that he had been unable to obtain any photographs of them. He had nothing more to say except that he thanked the meeting very much for the way in which they had listened to his paper. He knew that it was an exceedingly inadequate production and dealt only with one or two sides of a very large and most interesting question.

Mr. J. D. Crace writes: — "Much to my regret, I was prevented by illness from attending to hear Mr. Horsley read his paper. It was a matter of great disappointment to me, on reading a proof of the paper, to find the title practically passed by in the contents. Here is an architect of great ability and high position, with a subject of intense interest and importance to architects, 'Structural Color Decoration,' actually making no reference whatever to the effect of color on structure, the one side of the subject which vitally touches the work of the architect. There are passing references to colored materials, such as marbles, mosaic, bronze, but no word as to how the placing of these affects the structural impression of the whole for good or evil. What does it matter to the structural effect whether the pictorial work on the walls is painted in 'tempera,' in 'spirit fresco,' or in 'water glass.' The architect himself, a few yards distant, could not tell which had been used. The 'vehicle' is of no consequence to the painter, of none to the architect. But 'Structural Color Decoration,' that is to say, the disposition of color as affecting the structure, does deeply concern the architect. It is this part of the subject to which I have hoped that an architect of Mr. Horsley's ability would have devoted most time and attention, for it is not only the part which most concerns architects, but, unfortunately, it is the one of which they overlook the value. I have read and listened to dozens of papers by architects on the technique of mosaic, of fresco, of encaustic painting, of marble and woodwork, 'sgraffito,' plaster, and other decorative methods and materials; not one, that I can remember, on their disposition as influencing the structural effect. Methods and 'technical tricks' are all very well, and are good for the practitioner to be familiar with; but it is the distribution of the color-masses and color-values which affects the architecture. It matters little to the effect of the building (as architecture) whether the wall-paintings represent the 'Siege of Troy' or the 'Jubilee Procession,' or whether either be painted in 'tempera' or 'true fresco'; but it matters everything whether these works are so placed as to make the columns look thin, or so colored as to disturb the perspective, or so isolated as to remain disturbing patches. It is of much more consequence to the architect that the general scheme of color should be founded on recognition of the structural lines, that the color-values should be in the right places, and that the borderings and other ornamental features should be arranged, not with a view of 'breaking up the wall-surface,' but with careful consideration of their effect in expressing or explaining the surface, and in assisting the perception of structure. So far as it does, this color glorifies a building; where it does not do this, it abases it as architecture. A wall-painting may be full of admirable skill and yet be absolutely detrimental to the architecture which encloses it. Until architects will recognize this very plain fact, and will devote more attention to the influence of color on structural effect, leaving aside the technical questions which, after all, more concern the executive artist, we shall obtain no real alliance of the Arts. Let the architect get to know how color will affect his work, where it should be used, and why, and he will find the painter much more ready to listen to him than when discoursing of how to put it on."

THE EXHIBITION OF THE BOSTON ARCHITECTURAL CLUB.

THE impression produced on the visitor to this year's Exhibition of the Boston Architectural Club, at the gallery of the Boston Art Club, is quite as pleasurable as that which was awakened by the very notable one held three years ago in the gallery of the St. Botolph Club, and yet there is a very distinct dissimilarity between the evident aims of the committees in charge and a consequent unlikeness between the fruition of their efforts. Three years ago three ends were had in view and each goal was honorably achieved. First, it was sought to make the exhibition one that should appeal to the public even more than to the professional appreciation, and so architectural drawings, pure and simple, were ruled against with some strictness; next, a point was made of exhibiting positive rather than

possible architectural accomplishment, and so photographs of executed work were sought rather than perspective-drawings made before the buildings themselves had been built into shape, and, finally, some attempt was made to show what was being accomplished in the field of architectural-landscape design, which just then was beginning to excite a real popular interest. The result was an exhibition that appealed to the lay mind and filled the gallery with unprofessional visitors as we have never seen a gallery filled at any other architectural exhibition.

That was three years ago, and since then there has been no general exhibition in Boston, though there have been special exhibitions of individual work at the rooms of the Architectural Club itself, or in the gallery of some picture-shop. Consequently, people turn with some zest to inspect what the walls reveal, without that jaded feeling of being pretty sure that four-fifths of the work will be at least first cousins to four-fifths of the work shown a year before. After the lapse of three years, the chances are that the accomplished draughtsmen whose work won applause at the previous exhibition may have become busy with the practical side of work in their own offices and, so, finding no time to exercise their own skill, have had to make way for a younger group of draughtsmen, whose names are unknown and whose methods may be fresh and individual. A periodicity of three years has some very strong points to commend it.

The general impression of this year's exhibit is that it is one which possesses dignity and interest in a very unusual degree. The majority of the exhibits have, beneath the dress with which they have been endued for exhibition purposes — whether to please the taste of the public or to satisfy that of a prospective or an actual client — a framework of real architectural worth, and it is the perception that this architectural worth is there and will exist in the executed buildings, that it is not a mere matter of pen, brush and paper, clever draughtsmanship and knowing tricks, that causes one to feel that here is abundant evidence of real advance in architecture and that the various schools of architecture have not been founded and supported in vain. The trivial, the commonplace and the purely vernacular have either not been offered to the judges or else they had the courage to reject them. There is hardly a number which has not enough of real interest in it to justify the committee in giving it wall-space.

While the Exhibition is dignified and is fairly representative of work of a good type and the performance of men of ability, it is, distinctly, merely a miscellaneous gathering and as such typifies the average annual practice of the average architect, who has to stand ready to turn his thoughts and his pencil from a tenement-house to a church, from a cottage to a school-house, from a factory to a town-hall, possibly, if his practice is good, being compelled to perform these feats of architectural gymnastics all in the same day or, at any rate, within the limits of a few weeks or months. It seemed to us, as we found ourselves forced to change our point of appreciative observation as we passed from wondering over the housekeeping expense of keeping up a millionaire's "cottage" to admiring the quiet color-scheme of a church interior, and then on to an approving glance at some ingenious wrought-iron work, that it might be a very agreeable and desirable thing to hold, some time, an exhibition devoted to a single class of buildings — to churches, for example, or, at least, to group together buildings of the same class accepted for one of the ordinary miscellaneous exhibitions. At this exhibition there are shown half a dozen or so designs for churches which one would like to study side by side, instead of having to wander backwards and forwards from one side of the gallery to another. And speaking of churches, it has been a very noticeable fact that there are seemingly eras of activity in church-building, when every office, seemingly, has a set of church-drawings on the boards, and when this happens, the ecclesiastical flavor of an architectural exhibition is very pronounced indeed. This season appears to be an off-season in church-building, for, aside from Mr. Henry Vaughan's photograph of the rather barren and uninteresting stone church at Northeast Harbor, Me., church exteriors are confined to pencil-renderings of Mr. C. B. Dunham's Baptist Church at Arlington, and an unnamed study by Messrs. Clark & Russell.

Church interiors, on the other hand, are fairly numerous, from Mr. H. B. Pennell's large and elaborated water-colors of St. Peter's and S. Francesco at Assisi — drawings in which he has successfully curbed his penchant for violent blues and unnatural greens — to Messrs. Arnold & Locke's presentation of a most charming color-scheme for the decoration of St. Brigid's, in Jersey City, a drawing which is rather killed by its immediate neighbors.

It is in color-work that this exhibition is peculiarly strong and interesting, a full half of the numbers being treated in color to a greater or less degree. The one strong impression brought away from our first view was that created by Mr. W. R. Emerson's wonderful little drawings in colored chalks — common carpenters' chalks, he always takes pains to inform you, not the colored crayons to be found in the shops of the purveyors of artists' materials. Rarely has so glowing and rich a bit of color been produced as his little "Church Interior": it haunted us all night and at the next visit we went straight to look at it again, this time at shorter range, and so discovered that some part of the delightful harmony of effect and some reënforcement and blending of the tones had been secured by a trick — a trick with a purpose and, so, wholly justifiable. This and his other chalk drawings were framed and glazed, of course, but in place of using ordinary picture-glass he had chosen pieces of clear cathedral-glass of a strong saffron-colored tone and so had gained for his yellows, browns and reds a warmth and strength, as well as a depth and transparency, that could not have been obtained otherwise. It is a new idea, we believe, and seems to be one that might be adopted by some performers who are a bit color-blind. For instance, we can imagine that the violent and unnatural greens which are so much affected by Mr. H. B. Pennell and Mr. George F. Newton might give more pleasure to other people if they should be seen through a glazing of, say, a light bottle-green, and the chill that hangs about Mr. G. H. Hallowell's uncanny and geological sketch of "Dalmatian Houses" might produce shorter shudders if seen through a claret or madder colored glass. This drawing of Mr. Hallowell's and Mr. Emerson's "Church Interior" are about as far apart in method and result as they well could be, and yet both are most admirable and satisfactory drawings. The mannerism — whether original or merely imitative — shown in the "Dalmatian Houses" Mr. Hallowell abandons in his charming sketch of "Chartres" hung just above.

In the same corner is Mr. George P. Fernald's large water-color of the "Sala del Senato" in the Ducal Palace at Venice, an unusually successful piece of work; rich and warm in color and having about it no taint of scene-painting, it presents all the substantiality of a real room built of real materials. Admirable as is this drawing, Mr. Fernald greatly surpasses it in his drawing of the "Cloister at Taormina, Sicily," which we look on as a rather remarkable performance for an architectural draughtsman: it has the character of the work of a skilful painter who by some fluke had succeeded in painting an architectural subject so that the character of the architecture had neither been lost nor absolutely vilified.

The character of the water-color work hung seems distinctly to show that the present generation of architectural draughtsmen are abandoning some of the conventions of architectural drawing and, in their place, adopting, with modifications, some of the methods of the painters and decorators. The result is that the colored drawings at this exhibition have a greater meaning and interest for the occasional lay visitor than architectural water-colors used to have. What we mean can be noted by one who should take the trouble to pass from Mr. Fernald's drawings to a couple of drawings by the late Arthur Rotch, which for some unexplained reason are hung with the work of his successors, and Mr. Rotch's drawings were, in their time, held to have an unusual degree of pictorial merit.

But all these drawings we have referred to are based on subjects, mainly foreign, that appeal to the pictorial instinct of painter and architect alike. There is a difference between the invitation that is extended to an artist by the created result, time-worn and weather-stained, and that which is offered to him by the dry lines of an architect's orthographic drawings which he has got to humanize and vivify. In this kind of work Mr. Langerfeldt used to be, in Boston, the head of his class, and no exhibition was complete that was not adorned with half a dozen or so of his renderings. Ill-health and advancing years have seemingly put an end to his vogue, for none of his work is here, and there are only a few of the elaborate drawings made by Hughson Hawley, who for the New York offices renders the same sort of service that Langerfeldt used to render in Boston. It shows how the spirit of the times has changed that one turns from these drawings rendered in body-color, with over-emphasized highlights, to imbibe greater pleasure from observing how the younger men are arriving at effects by a simpler method. One of the most "knowing" of these methods is employed by Mr. Gregg in the production of a very charming sketch of the equally charming design made by Mr. J. T. Kelley for the "James Russell Lowell Memorial Gates" in Cambridge. Mr. Gregg seems to have produced his effect by using colored crayon on the back of tracing-paper on which the drawing was made, and then mounting on cardboard. If soluble colors in powder should be applied in the same way the blending of the colors would be still softer and less observable. There are so many specimens of Mr. Gregg's renderings hung in one part of the gallery or another that one is at first tempted to believe that the exhibition is his own private affair. But marked as his mannerism is, he successfully avoids monotony, and by using different media and fitting his treatment to the character of the material used in the building itself he succeeds in holding the interest of the observer, an interest which is about equally divided between the merits of the drawing and the merits of the design. There are so many draughtsmen nowadays who devote their time to rendering drawings for other people that it is not very often that an architect exhibits his own sketches, so that it is particularly pleasing that so excellent a type of this sort of color-work should be shown as that to which Mr. Guy Lowell treats us in his drawings for houses at Philadelphia and Beverly, Mass. The group of Mr. Wilson Eyre's freakish drawings has less of the air of unreality about them than is usually the case. It is a dangerous gift, this aptitude for turning out picturesque and "catchy" sketches, which attract by their unreality and charm by their unusualness. Mr. Emerson has the same gift, and we have heard it whispered that more than one client of his had wondered why his completed house looked not so very different from his neighbor's and so little like the original sketch that had captivated his fancy.

One other water-color drawing deserves to be mentioned, and that the "Night View of the *Examiner* Building," San Francisco, designed by the late A. C. Schweinfurth.

Architecturally, too, the exhibition is interesting. Lord, Hewlett & Hull's competitive drawings for the new Department of Agriculture Building, at Washington, have far more of merit in them than we were disposed to believe after seeing illustrations of their design in

the newspapers — and yet illustration in the daily paper is more and more sought after by architects! Nearby are the drawings of Babb, Cook & Willard for a house on Fifth Avenue, New York, sedate and carefully studied, but because of the slight rendering given to the drawings, not attracting the attention they deserve. At the other end of the gallery is Hawley's good rendering of Mr. G. B. Post's "New York Stock Exchange," a design which recalls the jibes that New York critics have cast on Boston because the architects of the Tremont Temple chose to crown their façade with the front of a Greek temple. Here Mr. Post has adopted a variant of the same idea and planted his great temple portico — octostyle *in antis* — slap across the middle of his building, without any particular association with the stories above it or below it. The portion of the wall of the building which runs up beside the portico, pierced as it is at each story with windows of the proper size for business-office usefulness, recalls the tale of the farmer who cut a hole in his barn-door for the cat and a smaller one for her kittens.

Near this are detail-drawings from the office of McKim, Mead & White and the Supervising Architect, the only things of the kind hung. Half way down the gallery and facing one another hang Ernest Flagg's drawings for the Naval and Military Arch — the, to us, most unpleasing design that the exhibition contains. Mr. Flagg has been "strenuous" to the last degree and his up-circling cornice, an abomination of abominations, seems to ape the pinned-up flap of a Rough-rider's slouch-hat, but seen only in elevation. The character in the hat comes out when the side or perspective view is had and the particular angle at which it is cocked determines whether it is becoming or unbecoming to the wearer. It seems to us that Mr. Flagg cannot have studied his design in perspective, else the weakness and disgraciousness of this particular form of crowning-member could hardly have escaped him. This weakness is not helped by the engaged, or rather embedded, columns with their pitiful fragmentary caps with which he has chosen to embellish the angles of his structure. The effort for originality has been strenuous enough, but something more than effort is needed to compel success.

The greater part of the remaining drawings come from Boston offices and most notable amongst these is the group of drawings which exhibit Cram, Goodhue & Ferguson's very interesting scheme for the "Sweet Brier Institute," in Virginia. One can only hope that the young ladies may eventually find themselves actually housed in real buildings that do not do injustice to the charm which Mr. Goodhue's marvellous drawings assure us they are intended to have. A large part of the work that comes from this office is Gothic in feeling, for Mr. Cram is amongst the most devoted upholders of the tenets of the Gothic school, but besides this he has a real love for Colonial work, and intended that this group should have all the charm and refinement of the best work in that most adaptable style. It seems to us, however, that he has been led a little astray by the importance of the group of buildings he was designing, and the consequence is that he has verged rather on Roman grandeur and has somewhat overpassed Colonial simplicity. Some of the buildings taken by themselves are satisfactorily Colonial, but the group, as a whole, has a too Roman air, just as the University of Virginia buildings are losing their original Colonial feeling and putting on a Roman aspect with the accretion of more and larger buildings.

It takes more than an esoteric appreciation of the good qualities of Colonial work to enable one to design successfully in that style. Mr. Cram has not quite succeeded here, and Mr. Ogden Codman, Jr., who is a pronounced devotee of the style and knows far more about it than most people, has not made an entire success with the two or three houses in the Colonial style which he exhibits: he fails when it comes to the roof, or rather the upper stories and the roofs combined. Here he has followed the type as it exists in the Georgian architecture of England, rather than that which is exhibited by the more generous and agreeable treatment presented by the best examples of Colonial work in this country. Of the several designers who exhibit buildings in the Colonial style, Mr. Guy Lowell, it seems to us, comes nearer the mark than any one. In no one particular is there a greater failing than in the handling of the gambrel-roof: several such are shown, and in every case, while the angles of the roof-slopes are in themselves sufficiently agreeable, yet in each case the building, as a whole, is "high-shouldered," — and a gambrel-roofed building cannot afford to be high-shouldered. The worst offenders in this particular are the various farm-buildings which Messrs. Coolidge & Carlson have designed for Mr. T. W. Lawson's stock-farm "Dreamwold," a name which is rather set at naught by the barrenness of the surroundings of the buildings and the general aridity of the buildings themselves. This is all the more unfortunate since in intention, and in many particulars of detail, the designers have shown a great deal of ingenuity and an originality that is fruitful in interesting isolated results. In later years, when plantations have grown and shingles have warped and grown gray, doubtless the name and the architect's intentions will be found more in keeping. These buildings are shown only in photographs, and form part of the the collection of photographs which have been grouped in a room by themselves, where they successfully kill one another. Almost all the photographs have one kind or another of platinum finish, and while a portrait platinotype is an admirable thing, one can stand about one in ten prints finished in that style in an architectural collection. These heavy smudges of shadow, shadow without gradation, too, exasperatingly obscure detail one would like to see.

There is very little in the way of miscellanies shown. Some interesting wrought-iron sign-boards for "Dreamwold," by Coolidge & Carlson, some andirons and knockers, by Mr. Russell G. Cook, and an inlaid oak and silver panel, by Mr. Oliver Ainsly, are amongst the most interesting in this class artistically, while the models for a narrow library-frieze by the same designer are amongst the amusing and ludicrous efforts of genius. A real effort has been made to collect plaster models, and we have the large models by Mr. Hugh Cairns of a pediment group for the Massachusetts State-house, and sundry bits of ecclesiastical sculpture for St. Vincent's, South Boston. Besides these is shown the model of Messrs. Peabody & Stearns's great country-house "Penshurst," for Percival Roberts, Esq., at Narbeth, Pa., which lends interest to the quarter-scale drawings of two elevations that are hung on the wall above, and the model of the fountains at the entrance to the Fenway designed by Mr. Guy Lowell. Judging by the amount of attention these models seemed to attract, visitors do not care much for this form of exhibit but derive a better idea of the designer's intention from the drawings.

Amongst the buildings which lend dignity to the Exhibition are the "Board of Trade Building" on State Street, by Messrs. Winslow & Bigelow, which promises to be unusually satisfactory, and the very rational scheme for the "Faulkner Hospital," by Messrs. Kendall, Taylor & Stevens.

For one fact we are profoundly grateful: if there happened to be any drawings representing the work of any converts to the erratic teachings of the believers in "l'art nouveau" they wholly escaped our notice.

NOTES AND CLIPPINGS

CHINESE COFFINS AND LUMBER. — In China probably more wood is used for coffins than for any other purpose. The coffins are made of lumber from 4 to 10 inches thick. It is not a high estimate to say that from 8,000,000,000 to 10,000,000,000 feet of lumber are annually thus utilized. — *N. Y. Evening Post.*

STEPS AT DOORWAYS. — The case of Davies *vs.* Tree, which resulted in a verdict for £150 damages against the proprietor of Her Majesty's Theatre in consequence of injuries sustained by a visitor to the theatre, should be instructive to architects who are ill-judged enough to plant a door on the top of a 6-inch step, so that the fact of the existence of a step is only visible from one side of the door (and may be overlooked even then) The plaintiff's case was not one of the best in the world: he was apparently in an excited state and in a great hurry to inquire as to some presumed mistake about his seats, and he went very quickly through a door which he said was pointed out to him by an attendant, but which in the evidence it was shown was not intended for the public, but only for the staff. In spite of this, however, the jury awarded him very substantial damages for the injuries which he received from a fall caused by the unexpected step in the doorway; and we think they were right. Of course one must sympathize with Mr. Tree, who has had to pay for the mistake of his architect; but perhaps the verdict will serve to impress upon some architects that it is a mistake, and a very stupid one, to place a step just under the closing line of a door, and that their clients may have to pay for it, and will not love them therefor. — *The Builder.*

THE New York *Evening Post* says that a house on Fifth Avenue, thirty-five feet wide, in process of erection as a speculation by a well-known firm of builders, was recently sold, when barely roofed-in, and, of course, without partitions, plastering, decorations or fittings of any kind, for five hundred thousand dollars; and it moralizes on this circumstance, to the effect that the modern millionaire dislikes the trouble of selecting a lot, having plans made for him, and going through the vexations, and, perhaps, delays, of building-contracts, and is coming to prefer a simple inspection of the assortment of ready-made houses offered by speculating builders of good reputation, from which he can make a choice according to his purse and his tastes; and says that, to meet this demand, the firms which make a business of building houses for sale have increased the magnitude of their operations, producing and offering dwellings ranging in value from two hundred thousand to five hundred thousand dollars, where, fifteen years ago, their maximum investment in a single house was usually not more than a hundred and fifty thousand dollars, and most of their buildings sold at forty to sixty thousand.

PRICES, however, have risen in New York within a decade or two, and it is fortunate for the building-firms that the number of very wealthy purchasers has increased also. Twenty years ago, sixty-five dollars a square foot was considered a high price for a corner-lot in the best residential section of Fifth Avenue. Now, one hundred dollars a square foot is the average price paid for lots in the middle of a block in that portion of Fifth Avenue which fronts Central Park, between Fifty-ninth Street and the Lenox Library. If we are not mistaken, this is by far the highest price for residential land in any city in the world. In London, there are so many places where fashionable people can live with credit, from the gloomy but aristocratic streets and squares of Mayfair to the pleasant regions around the parks, that land is not extravagantly costly in any of them; and, in Paris, there are so many beautiful streets within a radius of a mile or so from the Arc de Triomphe, all, practically, equally fashionable, that prices of lots do not average more than fifteen to twenty dollars a square foot. In New York, on the other hand, the area of desirable land for dwellings is small. The ever-present foreign element has long ago taken possession of the shore of the East River, and of the region immediately adjacent to it, and the border of the Hudson, up to the beginning of the Riverside Drive, is also mainly occupied by foreigners. Those who are rich enough to live where they like, and wish to be secure against disagreeable neighbors, are obliged, therefore, to take refuge in a comparatively small territory, of which the Central Park occupies the middle. Naturally, the land fronting on the Park itself is the most desirable, and, of the two avenues bordering the Park, Fifth Avenue, although less attractive in many ways than Eighth Avenue, on the other side of the Park, has the advantage of more established fashion. It is here, therefore, that the palaces of the Vanderbilts, and Astors, and Huntingtons, and Carnegies and others have been built, and, for many years to come, this will be the region to secure a foothold in which the millionaires from all over the country will pay almost any price.

MASSACHUSETTS and Maryland are the only States, out of the thirteen which originally formed the Union, which have preserved their original State-houses nearly unaltered. Massachusetts, rather than pull down or enlarge the building of which it is so proud, has spent six million dollars in providing an extension which is far larger than the original structure, but is so arranged as to change the effect of the latter as little as possible. Following this good example, the Legislature of Maryland has adopted a plan for adding to the State-house at Annapolis, which is far too small to accommodate the State business, an extension, about twice as large as the original building, but arranged to harmonize with it, and to change its character as little as possible. Annapolis is famous for its beautiful Colonial buildings, and it is a satisfaction to think that the architectural traditions of the place, as well as the historical associations of the State Capitol, are to be respected.

THE New York Superintendent of Buildings has stopped work on the new hotel for the Astor Estate, on the ground that wood was being used in finishing which, while intended to be fireproof, as the law of New York requires in all buildings more than one hundred and fifty feet high, is not satisfactorily so. While all architects will uphold Mr. Stewart in enforcing the law, a good many of them would like to know by what treatment wood can be made fireproof to his approval. The whole subject of fireproof wood is in a condition of deplorable uncertainty. Architects are showered with circulars and descriptions of "absolutely perfect" processes for making wood fireproof, alternating with "official reports," furnished by rival concerns, showing that these "absolutely perfect" processes do not fireproof the wood at all, but merely impart to it objectionable qualities. The tests made by the United States naval officers upon fireproof wood for use in ships of war have had, as they deserved, much weight with architects, but doubts have been cast upon the efficacy, or, at least, the permanency, of the results of the processes once favorably regarded. In this state of uncertainty, architects will be grateful to Mr. Stewart for an exact definition of what he considers an efficient process for fireproofing timber, and we do not doubt that the managers of the Astor Estate will be grateful also.

THE management of the St. Louis Exposition of 1904 announces a competition for a design, emblematic of the purchase of Louisiana by the United States from France, which can be used for a seal, medal, letter-head, poster or other purpose in connection with the Exposition. The designs may be in relief, or in black-and-white, or color, according to the preference of the artist, and must be delivered to Messrs. W. S. Budworth & Son, 424 West Fifty-second Street, New York, between Saturday, November 1, and Wednesday, November 5, 1902. They will be judged by a jury consisting of Messrs. Frederick Dielman, President of the National Academy of Design; John La Farge, President of the Society of American Artists; J. Q. A. Ward, President of the National Sculpture Society; Lorado Taft, President of the Society of Western Artists; C. F. McKim, President of the American Institute of Architects; Wilson Eyre, President of the Philadelphia Chapter of the Institute, and Professor Alcée Portier, President of the Louisiana Historical Society; and a prize of two thousand dollars will be awarded to the design placed first, which is to become the property of the Exposition management. Designs in relief must be, if circular, twenty inches in diameter, and if not circular the greatest dimension must be twenty inches. If artists prefer to submit a design for a poster, the drawing must be twenty-four by thirty-six inches, with a margin, increasing the full size to twenty-eight by forty-two inches. The style of lettering, if any, should be shown, and a design intended to be used for one side of a medal should show

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

also the other side. No designs will be received by the Exposition authorities in St. Louis, but competitors, who are to send their designs to New York only under motto or device, are required to send to Mr. Walter B. Stevens, Secretary, Louisiana Purchase Exposition, St. Louis, a letter, marked on the envelope "Emblem Competition," advising him of the submission of a design, and enclosing in a sealed envelope, a card, with the artist's name and address, and the device or motto with which the design is signed. A portion of the designs will be publicly exhibited, and these will be returned at the expense of the Exposition authorities, unless acquired for the Exposition. Those not exhibited will be returned at the expense of the owners.

ACCORDING to the newspapers, the fever for huge railway stations is at its height in Germany just now. The municipality of Leipsic, in connection with the Government railway administration, has entered into contracts for the construction of a station at Leipsic which will cost twenty-four million dollars; and enormous stations are said to be projected in other German cities. It is not likely that officials so enlightened and careful as those of the German railway administration would take such a step rashly, but experience in this country indicates that mere vastness in railway stations is anything but a desirable quality. The South Terminal in Boston, the largest railway station in the world, while it has, probably, no more track-room than is required for the various roads entering it, includes a large amount of other accommodation for which there is no need. The so-called "Midway," for example, which serves simply as a promenade, is far too vast. Even with its capacity practically diminished by one-half by the newspaper stands, soda-water bars, cigar-booths and miscellaneous structures scattered over it, most of the remaining space in it might have been transferred to the sidewalk outside, with advantage to the comfort of the public, as well as to the pockets of the stockholders. In the same way, the long and imposing range of ticket-offices is simply an expensive obstruction, only two windows, out of a row of something like a dozen, being used, even during the busiest hours of the day; and the vast waiting-room, also encumbered with flower and candy stands, would accommodate ten times as many people as are ever seen in it. Apart from the cost of enclosing and covering these useless spaces, they serve simply to fatigue and perplex travellers, and to provide a comfortable harbor and place of business for swarms of tramps, thieves and swindlers, who prey upon those who are entitled to the use of the station.

WE are so accustomed, in this country, to thinking that only "big men," such as "coal barons," "lumber barons," "iron barons," "beef barons," and "kings of finance," are capable of undertaking anything in the way of industry or commerce, that the idea of a Congress of ordinary mortals, to study the methods by which people who are not millionaires can own ships, and sail them profitably, seems almost dangerously disrespectful to the monarchs of the Trusts; yet such a Congress is to be held at Düsseldorf this year, beginning June 29, and continuing until July 5, the members of the Congress joining, after the sessions are over, in an excursion to the Kiel Canal and the cities of the Hanseatic League. The Congress is divided into two sections, one for ocean navigation, and the other for internal navigation, and in each branch technical and economic questions relating to it will be discussed. Among these questions are the deterioration of coal and coke by shipment; the dredging of harbors, and their flushing by tides or otherwise; the arrangement of docks; the employment of lighters; signalling in fogs; and, in the section of inland navigation, the mechanical propulsion of vessels on canals; the utilization of waste power at weirs, and the surmounting of great ascents. As usual in German Congresses, the proceedings are relieved by several incidental excursions, for which the situation of Düsseldorf is particularly favorable. For the afternoon of Tuesday, July 1, excursions are arranged either to Duisburg or Elberfeld; on the following Thursday there is to be an excursion up the Rhine to Cologne and the Seven Mountains; on Saturday members can choose between visits to the Krupp works at Essen, to the great dam at Remscheid, and to the Dortmund-Ems Canal. Saturday evening the three-day excursion to Kiel begins with the night journey to Bremen. Persons interested in the subjects discussed, although not members, may be admitted to the sessions of the Congress, under certain conditions, under the guidance of a member.

THE Rotch Travelling-Scholarship in Architecture has been awarded this year to Mr. J. F. Clapp, of Boston, and the second prize, given by the Boston Society of Architects, to Mr. Benno Janssen. Mr. Clapp is a graduate of the Architectural Department of the Massachusetts Institute of Technology and will go abroad well prepared for the work which he is to do.

THE *Russisch-Deutsche Bote*, a weekly journal, published in Berlin, with articles in Russian and German, gives an interesting account of the Trans-Siberian Railroad, on which continuous tracks are now laid from Moscow to Port Arthur and Vladivostock. It will be remembered that, for several years past, the line has been interrupted at Lake Baikal, across which passengers and freight were transported by steam ferry-boats. During the summer this transportation was easy and agreeable, and an attempt was made to continue it through the winter, by keeping the path of the ferry-boats clear with an enormous ice-breaker, the most powerful steamboat in the world, which could make its way through ice five feet thick; but this experiment did not prove very successful, and it was found advisable to continue the railway around the lake. This work has now been accomplished, and some difficult mountain engineering is so far complete that provisional tracks can be laid, although it will be two years before the permanent construction is finished. Meanwhile, however, the road is building up a large business, and developing the country through which it passes with great rapidity. Three years ago, the town of Novo-Nikolaievsk, near the crossing of the Obi River, had three thousand inhabitants. It has now sixteen thousand; while the village of Sretensk, not far off, has increased in the same period from seventeen hundred to eight thousand inhabitants, and new villages, which will soon be towns, are springing up around the stations. Coal-mines have been opened at three widely-separated points on or near the line; rich copper and gold mines are in process of development; agriculture is flourishing, and, next year, two beet-sugar factories are to be erected, besides flour-mills and oil-refineries. The total cost of the road, thus far, has been about four hundred million dollars, and the completion of the permanent way will add considerably to this sum. It is not surprising that the receipts from traffic do not yet pay the operating expenses of the line, much less interest on the cost; but the Russian Government looks at the development of the country, rather than immediate profit, and a line of this kind, connecting, practically, all Europe with all Eastern Asia, which has nothing to fear from competition, is sure to bring in a revenue sooner or later. When the permanent way is finished, passengers can be carried from London to Hong-Kong in about one-third the time that is now required for the trip by way of Brindisi and the Suez Canal, and at a much smaller expense; and the most inveterate British prejudice cannot prevent passenger-travel from taking that course. Whether freight will also be diverted from the water route remains to be seen, but it is probable that the steamers will continue to carry at least the bulky goods. So far as this country is concerned, the building-up of a great civilized community on the other side of the Pacific is a matter of the utmost importance. It has always been a question whether our trade in coarse cottons with China, in competition with England, was worth making great sacrifices for, but the trade which would naturally follow the development of Siberia, and which would include, probably, the exchange of copper, coal, wool, furs and oil for machinery, fine silk, woollen and cotton goods, canned fruits and provisions, and the other products of our varied industries which would be absorbed by a prosperous and civilized community, must ultimately be enormous.

THE lovers of nature will, we fear, experience another shock at learning that the highest waterfall in Europe, if not in the world, has just been made artificially, by digging a ditch from a mountain lake to the edge of a precipice, for the purpose of lighting a village, and driving the machinery of a factory. This cascade is situated at Vouvry, in Switzerland, in the Valais, on the edge of the lofty range of mountains which includes the Great Saint Bernard, Monte Rosa and the Matterhorn, and is more than three thousand feet high. It is, however, invisible to tourists, being enclosed in iron pipes, and manifesting itself only at the lower end, where it flows away through a set of turbines, which drive the ordinary dynamos used for converting energy for transmission to a distance.

DOMESTIC ARCHITECTURE IN ENGLAND DURING THE MIDDLE AGES.[1]—VIII.

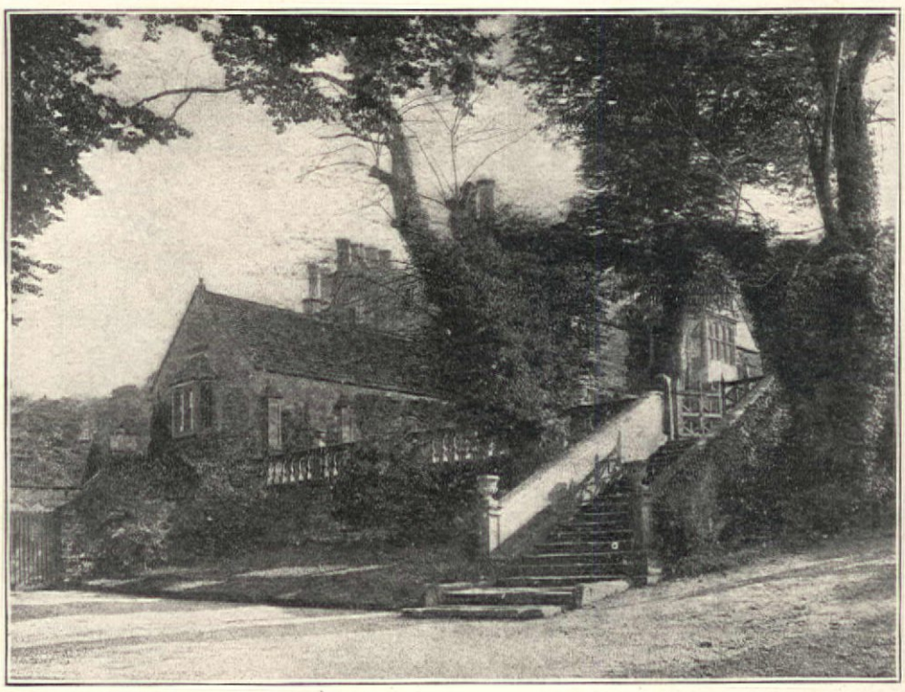
THE architectural features of the "Tudor" style are very distinct, essentially "Perpendicular" in character, but further developed, modified and enriched with added decorations.

In the earlier period we find turrets, octagonal in plan, highly ornamented, finished with ogee-shaped domes, the angle-ridges covered with crockets, surmounted with coronets as finials, or lions rampant supporting bannerets as vanes. Also expansive bay-windows extending from base to parapet, as may be seen at Henry VII's Chapel, the Augustine monasteries at Canterbury and Ipswich, at Oxford, Cambridge, Exeter, Haddon, Kirby Hall, etc. These are replaced later by the oriel-window, not less beautiful in detail, but much reduced in size and limited to one story.

Pinnacles are introduced in the gables, the roofs increase in height and pitch, as may be seen at Hampton Court, but in the time of Elizabeth we find the turrets disappearing altogether, the gables become moulded and diversified in outline, retaining the pinnacles; moulded and carved brick and terra-cotta become prominent substitutes for stone, in which we may see further Italian influence.

Permanent *fireplaces* having come into general use, we find a wonderful development in the prominence given to *chimneys;* they were built of brick cut, stamped and moulded in fanciful forms, many of extreme beauty, twisted reeds, zigzag and lozenge work, decorated with the fleur-de-lis, rose, crown and other ornaments in great variety of design.

Brick-making had greatly improved and brick with stone dressings formed the usual mode of building in the more important houses, and later we find the window-mullions, the strings and cornices executed in moulded brick. In the more ambitious works, like Hampton Court, we find beautifully carved heads of the Kings and the leaders of the times in circular panels executed in terra-cotta in the most perfect manner.



St. Catherine's, near Bath, Eng.

We also find the introduction of black or discolored brick in diaper patterns. These fire-stained bricks had, no doubt, been previously used in the hearting of the walls, but, as another evidence of the tactfulness and originality of the architects of the time, we find them converting apparently blemished materials into an effective means of decoration, many very striking examples of which exist at Hampton Court, in Bermondsey, and in the county of Kent, generally. These are in various forms of lozenges, diamonds, cross-keys, intersecting triangles, globe and cross, arcades, balustrades, dates, etc. The effect is most marked and picturesque, and shows the same tendency to enrichment by surface-decoration that, in more pretentious buildings, is secured by panelling.

The prevailing use of the four-centred, or "Tudor," arch is another salient feature, as distinct in fact as the two-centred Gothic arch itself, becoming more and more depressed as the period advanced. Not infrequently semi-elliptical or three-centred arches are met with, till, finally, in the later buildings of the Elizabethan age the arched form in the lights of windows was replaced by the horizontal head and transom, the lintel of pre-mediæval times supplanting the arch. These many-storied windows were filled with rich stained-glass in leaded lights of more or less intricate design, emblazoned with the crests and armorial bearings of the founders or owners. This is called heraldic glazing, the idealization of adjuncts deemed necessary in preceding ages; the stern emblems of the wars in which their forefathers had won renown and broad domain were now trophies of the past and features of decoration. Much of this is preserved at Hampton Court, Windsor, Warwick, and in many private chapels and chantries and other notable buildings.

In referring to examples of the grandest specimens of the windows of this period, it is impossible to avoid reference to buildings of more or less ecclesiastical character, as private chapels, etc.; and as one of the most marked features of the period is the "fan-groining" of its stone roofs in close juxtaposition with its grandest windows and glorious open-timber roofs, it seems not out of place to call attention to it as contemporary architecture.

In Henry VII's Chapel, contiguous to Westminster Hall, we have the most striking and magnificent example of this distinctive vault (erected between 1503 and 1512), the climax of stone groining. The vaulting-surfaces are hollow conoids, covered with a mazy network of fine ribs and serial panelling, from which depend fan-shaped pendentives of great size and richness. This is well shown in ordinary illustrations, but neither words nor illustration can convey an adequate idea of the beauty in execution of this wonderfully distinctive characteristic of mediæval architecture in England during the Tudor period.

The doorways are very pronounced, similar in general design to those of the Perpendicular period, more ornate with the pride of the time — heraldic devices, mottos or legends. The two-centred pointed arch had gradually become more and more depressed and was replaced by the Tudor, or four-centred, arch peculiar to the period; the outer and "label" mouldings were carried up square above the springing-level of the arched opening and across the head; the spandrels thus formed were filled with panelling enriched with carvings of the Tudor rose, crowns, portcullis, monograms, etc. These doorways were often projected and flanked by small semi-octagonal turrets with open panelling across the top.

Perhaps, however, one of the most characteristic features of Tudor architecture is the tendency to uniformity in external treatment as distinctly at variance with the spirit of earlier work. The central feature, usually the entrance-doorway, is strongly marked and more or less elaborated, but in the extension of the front and wings, one side matches the other, window for window, bay for bay, tower for tower, even to the extent of replacing windows with counter-balancing blank panelling. To this is added the ongrafting of Classic forms copied from pre-mediæval sources, which, however incongruous, produce effects of wonderful picturesqueness, as may be seen at Hatfield, Hardwicke, Wolterton, Burghley, etc.

We find, too, broad terraces with flights of stone steps flanked by ornamental stone parapets pierced with interlacing patterns, pedestals surmounted by griffins carrying shields or finials, all of very characteristic and quaint design peculiar to the period. Spacious gardens with broad walks, parterres bright with flowers, shrubbery, etc., are now common. Beyond the low surrounding garden-walls and through the open gateways stretch long avenues of trees, with views over broad domain of park-land, clumps of elm, oak, beech, ash, sycamore, chestnut, etc., the glades peopled with fallow deer and the elms alive with noisy colonies of rooks.

Hatfield, Haddon, Panshanger, Compton-Wyngate, Brereton, Kirby, Audley and Houghton Tower, Woodstock, are typical examples of the period and are all readily accessible to the student and well illustrated in Gotch's "*Baronial Halls*" and other works.

England is, indeed, rich beyond all other countries in examples of the stately and picturesque mansions of the Tudor period. The ways of olden times have not yet quite disappeared, for we find so recently as December, 1900, that Lord Edward Cecil, on his return from the seat of war in South Africa, was received at his ancestral hall at Hatfield with the picturesque rejoicings of feudal times. His carriage was escorted by tenantry of the estate bearing torches, and the family group, headed by the venerable Marquis of Salisbury, awaited his arrival on the steps of the old mansion to bid him welcome home again.

Hatfield is, perhaps, the most magnificent example of the late Tudor or Jacobean mansion of its kind to be seen anywhere; certainly none is more perfect. It was originally the palace of the Bishops of Ely and by them rebuilt and enlarged at the end of the fifteenth century; was confiscated by Henry VIII and made a

[1] Continued from No. 1374, page 29.

Royal Palace and occupied subsequently by Edward VI and Elizabeth. It was exchanged away by James I and came into possession of the Cecils at the commencement of the seventeenth century and was by them partially rebuilt and altered in a style that may be termed Late Elizabethan or Early Jacobean. In 1835 a fire destroyed a portion of the west wing, but this was rebuilt "after the original design."

The buildings occupy a parallelogram of about 280 feet long by 70 feet wide, the extreme length along the south front being 300 feet. The design is almost exactly symmetrically arranged, with large windows and bays. The hall, which is 50′ x 30′, is a good example of the late Elizabethan hall with its grand screen and coved plaster ceiling divided by richly decorated beams on boldly carved corbels, and may be named as an early departure from the open-timber roofs which were one of the glories of the early Tudor period. The walls are wainscoted and decorated by carving attributed to Flemish artists. The grand staircase[1] is another bold and very ornate feature. The gallery is 163 feet long by 23 feet wide and 16 feet high; the chimneypieces are very massive, with fire-dogs to the grates. The walls are grotesquely panelled and the ceiling richly panelled in plaster. This gallery is full of works of art, coats of mail and rare old furniture, including Queen Elizabeth's cradle. King James's room and the Library are also very fine rooms.

The introduction of ornamental plaster ceilings, modelled and moulded by hand, is one of the salient features of the late Tudor period, and is well illustrated in Gotch's splendid work on the "*Baronial Halls of England*."

There is still another style of building that, though it took its rise in the previous period, became very general in certain districts, and is especially illustrated by the many well-preserved examples of the old half-timbered houses erected at this time. These houses are found scattered throughout western Lancashire, Cheshire, Shropshire and along the banks of the Severn, Wye and Avon, and again in Kent. (See illustrations from the *Builder* and *Building News*, drawn by Maurice B. Adams.) These half-timbered houses were built of

Old Houses, Warwick, Eng.

heavy oak framing, mortised and pinned together at the joints, filled-in flush between the timbers with brick or lath and plaster. The work of similar class in the Midland Counties is of earlier date. There are numerous fragments of these old houses dotted all over these districts, many of great interest, sometimes surviving in a picturesque gable or two, part of a more modern barn, that must be left to the inquiring traveller to discover. Many most interesting examples are illustrated in Henry Taylor's "*Old Halls of Lancashire and Cheshire*," in Gotch's "*Baronial Halls*," Nash's "*Mansions of the Olden Time*," "*Picturesque Europe*," and in the publications of the *Builder*, the *Building News* and other current works.

The growth throughout the country of these old halls and mansions marks the rise in the wealth and consequence of the "middle," that is, the professional and commercial, classes of the period, as distinguished from the old nobility of feudal times and other great landed proprietors whose wealth was inherited, on the one hand, and the laboring classes on the other. The style of building is altogether different; it has no connection with the feudal times, there is no family sentiment, no pride of ancestral tradition or historic reminiscence about them. They were erected by self-made men, merchants and others, at a time when architectural taste was decaying — in times of peace and commercial prosperity — to secure to themselves such comfort, ease and luxury as they could afford according to the manners and ideas of the time. It is still truly historic or evolutionary architecture; that is to say, it is not a copy from preëxisting work, but the bona-fide growth and outcome of the life of the times.

We find in these half-timbered houses the large mullioned and transomed windows of many leaded lights, in which plain shields or circles charged with simple devices replace the heraldic glazing of the houses of the older families; huge fireplaces and quaint chimneys devoid of ornamentation, overhanging stories, and gabled roofs covered with the split flagstones of the neighborhood, or sometimes tiles in clay countries. Of these buildings we find beautiful and very perfect examples in Worsley Old Hall, near Manchester, erected in 1580; Alderley Edge, 1521; St. Peter's Hospital, Bristol,; Butchers' Row, Shrewsbury; houses in Warwick; the Oak House, West Bromwich; Speke Hall, near Liverpool, moated, erected 1593; the "Hall in the Wood," Bolton, 1598; Agecroft Hall, Cheshire, wood and plaster, 1561; Bramhall Hall, Cheshire, 1521; Darcy Lever Hall, near Bolton, 1541; Hanover House, Tunbridge, Kent, 1620; Holford Hall, Cheshire, moated, 1560; Little Moreton, Lancashire, moated, 1559; Ordsall Hall, Retford, Notts., brick and timber with curious oriels, 1560; Windsor Castle, the Curfew Tower and Horseshoe Cloisters, 1540; Severn End, Worcestershire; hospitals at Leicester, Coventry, and many others easily accessible and well illustrated by photography and in works before named.

This style of building, like the more pretentious stone buildings before referred to, continued with more or less modification in remote districts well into the Stuart period, developing the Jacobean style; but practically the mediæval style of architecture died out with Elizabeth, the last of the Tudors.

During the civil wars in the middle of the seventeenth century, the time of Cromwell, a great many of the old castles, like Kenilworth, Woodstock, etc., were more or less dismantled, destroyed and laid waste and ceased to be used as places of residence. Their ivy-clad ruined towers alone remain to this day to tell us of the lofty grandeur of those venerable old castles, the magnificence of their lordly owners and the warlike times in which they were built, and, alas! also of that cruel, barbarous reactionary period, the period of religious frenzy, during which social and political England was convulsed, laid waste and blighted with internecine wars.

We have now traced the parentage and birth of domestic mediæval architecture in England; illustrated its growth and triumphs, its brilliant springtime, its glorious summer and its golden autumn. But could it ever have been more beautiful, more fascinating, more intensely lovable than it now is in its gray, solemn ruins, mantled with the ivy of centuries? We see them as they are; we can picture them as they were, and, by the light of these somewhat discursive notes, we can re-people them with their lordly owners, reënact the stately pageants, the gay tournaments, and the pomps and circumstance of the times during which they were built. These now silent towers and crumbling ruins are the sole remaining witnesses of what England was during the Middle Ages. THOS. C. SORBY.

[To be concluded.]

[1] A good view of this staircase is given in Nash's "*Mansions of the Olden Time*."

THE INIQUITY OF THE ENGLISH LAW OF ANCIENT LIGHTS.[1]

I WILL not occupy your time with any preliminary remarks, but commence at once *in medias res* and say, my contention and conviction are that the state of the law in England today with regards to rights of light is little, if any, short of an iniquity.

The Prescription Act (2 and 3 Will. IV. c. 71, s. 3) enacts "That when access and use of light to and for any dwelling-house, workshop or other building shall have been actually enjoyed therewith for the full period of twenty years without interruption, the right thereto shall be deemed absolute and indefeasible, any local usage or custom to the contrary notwithstanding, unless it shall appear that the same was enjoyed by some consent or agreement expressly made for that purpose by deed or writing."

The result in practice being that if where two men own two contiguous plots of ground and one owner wants to build and does build at once and the other owner does not want to build, then notwithstanding that he may have every intention of building eventually — if owner number two postpones his operations for nineteen years he is unable to use his own land in accordance with his desire without being hampered by certain so-called rights his neighbor has acquired to access of light to his windows and other openings over number two land. In effect, my neighbor can dictate to me at what period I am to build on my own land by building on his own.

Again, if both owners build simultaneously, but A builds a more lofty edifice or a longer than B, B, if he is ever to increase the size of his building, must do so within nineteen years of A's completion or be practically debarred from so doing altogether, regardless of whether B has any need or wish or even whether he is able to extend his premises within that time.

One more illustration, this relating to old buildings. In an urban neighborhood, a large factory is required that will give employment to hundreds or thousands of hands, or a public authority wish to erect a town-hall, baths, library, workmen's dwellings or other institutions of public utility: both are hindered and harassed or altogether frustrated in their purpose because buildings not even on the same side of the road, and possibly the most wretched hovels, will be deprived of some light, ignoring the fact that the light which had been enjoyed was not provided for by the owner of the dominant tenement or at his expense or even by his forethought, but simply because the owner of the servient tenement had no need in the past to use his land in the same way or carry his building to the same height and extent as the owner of the dominant. Thus the most useful and necessary building we have imagined is curtailed in accommodation, marred in its usefulness and shorn of much of its beauty

[1] Portions of a paper read by Mr. Walter C. Williams, Solicitor, at the meeting of the Society of Architects on March 20, 1902.

for what, to my mind, is an inadequate reason. One could suggest innumerable cases of a kindred nature, but it seems needless to do so when speaking to an audience of practising architects who are, of course, acquainted with the salient features of the law on this subject and its practical results.

I cannot see the rule has any foundation in natural justice. I cannot see that it is defensible, either ethically or on the ground of expediency. Why should not a man have to make his own provision for the light to his building over his own land or over the public way? If he will not provide an open space on his own land to light his building, why should I have to provide one on mine for him, at any time, earlier or later? Now, how can an owner prevent his neighbor acquiring a right of light over his land? In one way, and one way only, and that is actual obstruction.

He may protest in the most emphatic and solemn manner, but it avails him nothing; he may give notices, but they give him no protection. No, wherever his neighbor has an opening in his building, overlooking his land or buildings, he must erect a hoarding (if he do not wish to build permanently) opposite to it.

The hoarding may have to be 60 feet high and 500 feet long, may be a hideous eyesore to the surrounding property, may be a most oppressive, even ruinous, expense, but up it must go, and must be retained there for a full year, for Section 4 provides that an interruption to be valid must be for one complete year. Hence you will see, gentlemen, that as soon as light has been enjoyed for nineteen years and one day there cannot be an interruption of one clear year before the expiration of twenty years from the time of its first enjoyment, though the owner cannot bring any action until the full twenty years have elapsed. It is obvious that in some cases this remedy may be as costly as the value of the land.

Even if expense do not stand in the way, in London (and, I believe, in many large provincial towns and cities similar rules are in force), but in London should such a hoarding be erected for the purpose indicated it becomes, under the London Building Act, an irregular or temporary structure, and requires the license of the London County Council or local town council for its erection or retention, and should this license be refused, as it well might, the owner is in this delightful position: he finds he is by one Act of Parliament precluded from doing the very thing which, by virtue of another Act, is the only thing he can do to protect himself from the encroachments of his neighbor.

There is yet another anomaly and hardship. A man may be entitled in remainder expectant on the life of a young or middle-aged tenant for life, say, stepmother or brother, only a year or so senior. During the life of the tenant for life rights to light may be acquired which the remainder man has no means whatever of preventing or resisting, because, as I have pointed out, he must actually physically obstruct the view of the poaching tenement; but, as tenant for life, he has no authority to enter on the land about to be affected to carry out the requisite work. It may be the remainder man was an infant, *non compos mentis*, or abroad; it may be the tenant for life has acted in collusion with the building party; all this notwithstanding, the remainder man has his inheritance depreciated in value by the acquisition of these adverse rights that he was powerless to prevent.

The same with a landlord whose tenant allows rights of light to be acquired over the demised premises. . . .

The easement of light, however, differs in its nature from other members of the family. Rights of way and rights of common may well be presumed to have been granted, as such easements may be almost of necessity, and, moreover, conduced to the convenience of the actual or supposed grantor as well as of those who enjoyed them. They are also always for the convenience of the many as against the strict right of the single owner, whereas the right of light is for the sole benefit of the single owner at the expense of all his neighbors.

Again, a riparian owner is entitled to the undiminished flow of a stream over or by his land, and if an owner up stream interferes with the flow in any way the property lower down is damaged, and that independently of any act on the part of its owner. But the claimant of right of light must himself have done in the past the very thing he now complains of in his neighbor, viz., have interfered by his own building with the access of light to his neighbor's property.

I contend that this judge-made rule is not founded on any consideration of natural justice or ground of public utility. On the contrary, the voice of justice seems to me to say that a man must light his premises over his own land or the public way; and public utility there assuredly is none, as the benefit is always to an individual at the expense of others. . . .

Before concluding I must refer to the laws of some foreign countries.

Now in Scotland our English rule has never been accepted. Erskine says, in his "*Principles of the Law of Scotland*": "This servitude cannot be constituted by prescription alone, for though a proprietor should have built his house ever so low, or should not have built at all for forty years together, he is presumed to have done so for his own convenience and profit, and therefore cannot be barred from afterwards building a house on his property or raising it to what height he pleases unless he be tied down by his own consent." Another writer says: "The theory in Scots law is that a proprietor is only bound to provide light for his own property, and any open space he may have is not to be reckoned on by his neighbor."

In Ireland also a man had to provide his own light as well for his land. The Irish law, however, is now assimilated to our own by Lord Carew's Act in 1858.

In the United States in 1837, shortly after the Prescription Act was passed, an American judge — Judge Bronson — expresses himself thus: "There is, I think, no principle upon which the modern English doctrine on the subject of lights can be supported. It is an anomaly in the law since the English doctrine of ancient lights has been repudiated in our courts. It cannot be applied in the growing cities and villages of this country without working most mischievous consequences. It has never, I think, been deemed part of our law." And he then refers to Kent's "*Commentaries*."

In 1893 the New York Court of Appeal held that an owner of property may place his windows overlooking his neighbor's premises, but the neighbor may build to the extremity of his land nevertheless.

In France it is provided that a man may not have a straight view or a window for sight or balconies or other projections on his neighbor's estate unless there is a distance of 19 decimetres between the wall on which they are made and the said estate; nor a side or oblique view on the same estate unless there is a distance of 6 decimetres.

The Italian code is similar, but the distances are slightly less.

Lower Canada maintains the French rule.

In Sweden a man must not construct windows nearer than 7 feet 9 inches to his neighbor's land.

So you see in none of these countries can a man rely on his neighbor for his light, but must make suitable provision for himself. Hence we see another example of the isolation of our beloved country; whether it be a splendid isolation, however, is a matter on which a man may "hae his doots."

Now, having briefly considered the state of our law as to light, and briefly how that state came about, and having heard the opinions which some of our judges entertain of the doctrine, and having taken a cursory glance at the law of other countries, I ask you, gentlemen, are you satisfied with the law of your own? If not, there is one remedy, and one remedy only — legislation.

This legislation need not be fantastic or complicated; it could be simple but at the same time effectual, both practical and practicable.

I would suggest an enactment providing that no further rights of light across another's land should be acquired. That existing rights should be extinguished: —

1. As to freehold, at the end of fifty years.
2. As to leasehold, at the expiration of fifty years, or the existing term, which period should be the shorter.

This would entail no hardship on any one, would do an injustice to no one. The man who had built would still have all that he paid for, his land and the materials on it, and the owner of adjacent land would enjoy his own in his own way without being jeopardized by the operations of his neighbor.

I can conceive some objection to this in the case of abnormally high buildings, but this might be easily provided for by giving owner of adjoining building, over, say, 50 feet high, a right — which, indeed, I think they would have without special provision, under the maxim, "sic utere tuo ut alienum non lædas" — to compensation, not for obstruction to their light *per se*, but for any general damage that might be actually proved in each case by appropriate evidence, as in suits to abate a nuisance.

It now only remains for me to acknowledge my obligation to Mr. Blythe's paper, read before the Incorporated Law Society, for the references to some of the older cases and for information as to foreign law, and to thank the Council of this Society for having honored me by the invitation to open this discussion, and you, gentlemen, for the patient attention you have given to my remarks.

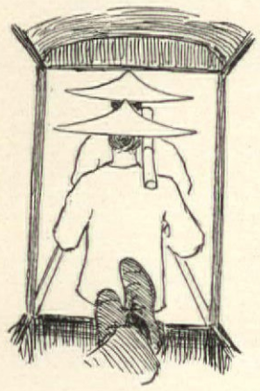
JOURNAL SKETCHES IN CHINA.[1]—IV.

CANTON.

As soon as the steamer made fast to the wharf a guide, who turned out to be a woman, was secured for me. Off we started in a drizzly rain through a maze of narrow streets to find the foreign quarter, where resided a few gentlemen to whom I had letters. A charming feature of the East is the unbounding hospitality of foreign residents; even the English become more like human beings when separated from their snug little island. Tempting as the proffered hospitality was, I had to decline, as my time was exceedingly limited and it was necessary that I should get as near the Chinese as possible. This was fully understood, and I was directed to a hotel on the other side of Pearl River which was in the midst of Chinadom and was kept by a Portuguese who had married a Chinese. I was also given a letter to Mr. Sampson, the Director of the Government school. Off we started again, my female guide appearing quite as masculine in her jacket as the other sex did with their smooth faces and hair-braids down their backs. A boat was engaged, literally the man's house, and he and his wife rowed us across the river. Opportunity was then offered for a further examination of this forest of boats that lined the shore in a deep layer for miles. It was interesting to peer into some of them and discover little domestic scenes; cooking, tinkering, children playing and, indeed, just those activities that one might see in a busy street. We finally reached the hotel, which was certainly all I could desire in the way of proximity to the Chinese. With the exception of the Portuguese landlord, I was

[1] Continued from No. 1377, page 53.

apparently the only foreigner in the region and the only guest at the hotel. I say hotel, for thus it was labelled on the outside. It was with regret that I gave up the comforts and quiet of European civilization in the Orient, with its tennis-courts, flower-gardens, whist, and the delights with which the English and Americans surround themselves. I use the word European, for the avoidable noises we produce in America are only equalled, not exceeded, by the Chinese with their fire-crackers, ear-piercing trumpets and gongs.



So-called Chair in which one travels.

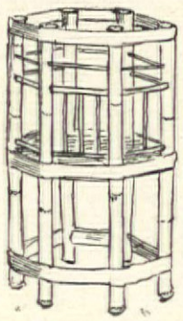
The landlord arranged for two palanquins, or chairs, as they are called, one being for my guide. Each of these was borne on the shoulders of three men, two in front and one behind. My first quest was for the Government school and Mr. Sampson, and away we went at a fairly rapid pace, through such sights, sounds and odors as one might expect to find on some other planet and a very addled one at that. The city of Canton is much cleaner than Shanghai. The narrow streets are paved with stone or big square bricks, and the buildings, mostly of one story, are all of brick, with thick, solid-looking walls. Narrow shops, or cells, consist in front of a wide doorway and a wide window through which one, without entering, may haggle for the goods displayed. The shops are rather dark within, as the streets are narrow, and overhead reed mattings, supported by wooden frames, provide a constant shade from the sun's rays, which in the latitude of Canton pour down with tropical fervor. The vertical signs with their gilt characters form a varied fringe on each side of the narrow, irregular streets, which in many cases are hardly wide enough for two palanquins to pass. The same activity is seen here, despite the heat, as in Shanghai. The crowded thoroughfares are still more congested by the various artisans carrying on their occupations in the middle of the streets, in fact, taking up both sides. The peripatetic carpenter, with his stock of tools and lumber, over which one has to step; the petty traders and fabricators, crowding the narrow lanes in a way that would not be tolerated in our country for a single moment; the hammering, planing, rice-pounding, the loud din of the coppersmith, the musical clink of the blacksmith's hammer, the multitudinous variety of weird street-cries, with the occasional rattling outburst of fire-crackers, all made up a perfect pandemonium. The three senses of sight, hearing and smell were incessantly assailed by interesting, ear-splitting, and disgusting impacts. It was all intensely absorbing and I had my eyes everywhere.

We had a long distance to go to reach the Government school, and the crowds through which we forced our way were anything but friendly. If the Chinese of Shanghai appeared rude and indifferent, the Cantonese appeared decidedly hostile, nor could I wonder at this attitude, for at the time of my visit the French were threatening their southern frontier and Manchu troops were passing through the city on the way to repel the expected invasion. Aside from this, there was not a man who was not more or less familiar with the history of the opium war and the calamitous horrors which accompanied it, when humiliation and death had come upon them in fullest measure from the hand of the hated foreigner.

On reaching the school I presented my letter and was received very kindly by Mr. Sampson, who at once conducted me to the recitation-room, in which were five students. They all rose and said, "Good morning," like a set of automatons. Mr. Sampson requested them to read in turn from an English history and this

School, Canton.

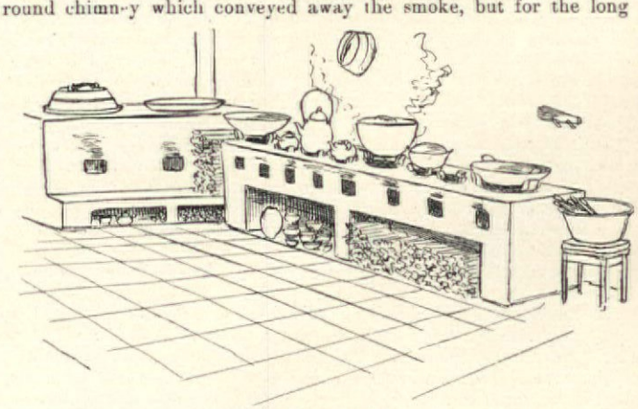
they did fairly well. On my expressing surprise at the smallness of the class Mr. Sampson told me that one of his greatest difficulties was to impress upon the pupils the necessity of punctuality; some days there would be a dozen or more in the class and at other times none. Here, in a city of a million of inhabitants, was this one little school to satisfy the demands of the people for a knowledge of foreign studies. I could not help contrasting this with Tokio, having the same population, with its great University, every student of which becomes well versed in English before entering; the great Medical College, every student of which has to understand German before entering; the College of Engineering; the Foreign Language School, where a knowledge of French, German, Russian and Chinese is required; the School of Chemical Technology; the Military and Naval College, all with their foreign professors and instructors, and the modern languages taught in the normal and high schools, and the Nobles' School, as well, and thousands upon thousands of Japanese students punctually attending the classes of these institutions until graduation. What a contrast! And yet many English writers regard this hunger for knowledge with contempt, and esteem the Chinese as superior, basing their judgment on their own leading characteristic as a nation of shop-keepers, which quality has dominated nearly all their foreign wars and their acquisition of foreign territory. Here in China they find their match in the astute Chinese merchant, who is equally honored and respected with them.



Baby's High Chair.

The school consisted of a few private dwellings which had been brought together into a series of connecting rooms by simply knocking a few holes through the thick partition-walls of the various houses alloted for the purpose. A plan of Canton with its houses would resemble a gigantic honeycomb, the cells being quadrangular instead of hexagonal. Mr. Sampson kindly permitted me to roam over the premises at will and I secured a number of sketches. Many of the features were quite unlike those of the Shanghai house, though the reception-hall was planned like the northern one and the minor details of work and ornament were somewhat similar. I may add in passing that the people are different, their language is different and a man from Shanghai is not only regarded as a foreigner, but is rather brusquely treated as one. In Shanghai I had acquired a few expressions such as "thank you," "good-morning," "good-by," etc., which had always been understood when I ventured to use them; here in Canton not a single expression was understood. I was told that the two languages were as different as Spanish and Portuguese or Italian. They all use the same characters in writing, however. These characters are conventional symbols, each one representing a word or an idea and hence called ideographs. Over this vast Empire, as well as in Korea and Japan, the written language is the same. Throughout the Chinese Empire there are a number of languages and hundreds of dialects. The characters, to the number of thousands, which have come down from the dim past have the same meaning. The Chinese must have had, early in their history, the example of phonetic writing on their western borders, but have persisted to the present time in using this archaic and cumbrous device in expressing their thoughts.

My first hunt was for the kitchen, for here is an ethnic feature associated with family life that persists without change for generations. It is this feature that is rarely described or figured in books, and for that reason I made a special effort to secure sketches when opportunity offered. The kitchen range was long and had accommodations for many cooking-pots. Each opening had three spurs, or supports, so that the vessel was held some little distance above, as in the little braziers in Japan. Here, also, I saw in an open place under the range a number of braziers or pottery cooking-devices in which charcoal was used for fuel; in another space wood was piled. The rice-kettles were large and somewhat shallow; the cover had the appearance of a shallow tub inverted. Mr. Sampson informed me that the Chinese often utilized the steam arising from the boiling of rice in cooking other kinds of food In the rice-boiler range was a round chimney which conveyed away the smoke, but for the long



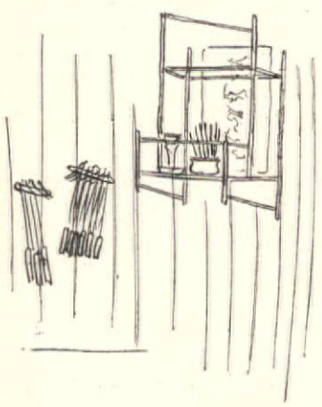
Kitchen Range, Canton.

range I failed to note a chimney, if there was one. The walls of the kitchen were sufficiently blackened to indicate that no flue existed. At the end of the long range was a large jar in which were various wooden ladles for convenient use, and above a huge bamboo brush, or stirrer, was resting on two pegs. The materials used in the construction of these ranges were stone, brick and cement and appeared

strong and durable. Here, however, the differences ceased. The resemblances to the Shanghai kitchen were again seen in the same amount of dirt and disorder; the floor was grimy with dirt — street dirt tracked in — broken jars lying about and everything indicating a shiftlessness past belief. At the opposite end of the kitchen was a

Kitchen, Canton.

little shelter where sat the cook, who smoked his pipe while waiting for the kettle to boil. It was amazing to see the tumbled-down shanty provided with the most elaborately designed window-sashes, the details of which I had no time to sketch. The carvings over the door and the various intricacies had all to be omitted in these rapid memorandum outlines. The kitchen shrine was high on the wall near the rice-kettle. It was a rough bamboo framework capable of holding a device, in which candles were burning; near by were a number of candles made on long sticks. These were stained or painted red and at the ends of the sticks cross-pieces of bamboo were tied so that they could be hung on a peg, as shown in the sketch. A number of Chinese gathered about me curious to know what my purpose was in sketching, and Mr. Sampson, who spoke Chinese, asked them what they thought I was drawing, and they replied that the foreigner was about to build a house and was getting ideas how best to do it.



Kitchen Shrine, Canton.

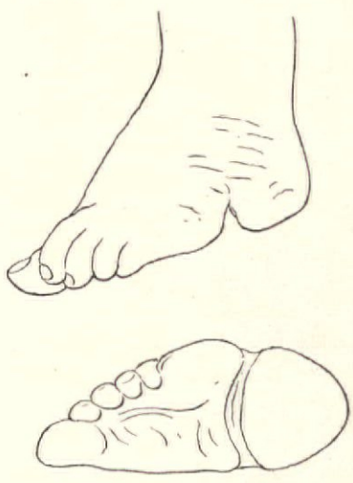
From the kitchen other rooms were visited. One room, evidently a study, had a very large window opening into a little garden. On the garden-wall opposite the window was a strip of paper on which were written four Chinese characters, which after some trouble were rendered into English as follows: "May fortunate light illuminate the garden." The translation of these inscriptions in China always comes as a surprise to the foreigner. Many of them express the highest emotions — a love of cleanliness, exalted piety, tender compassion, etc.; and then one contemplates the people with their cruelty, their filth, their ignorance, the abject position of women, and it is realized that the inscriptions are words — empty words, conveying no more meaning to them than if they had been written in Coptic. I suppose it may be justly said that the moral teachings of Christ have in the same way lost their potency among Christian nations. Dr. Gustave Schlegel translated an inscription in a Canton gaudy boat which read, "Among pure breezes we enjoy the moonlight." It may be said with truth that the Chinese, in the cities and villages at least, are deprived of this enjoyment. I was shown a few bedrooms, and here, as in Shanghai, the bedsteads were ponderous affairs having a high frame with tester above and curtains pendent.

The sanitary arrangements were simply abominable. In the three thousand years and more that the Chinese have been a nation, natural selection has rooted out all those who could not survive these flagrant violations of all sanitary laws, the survivors being evidently immuned against microbes that would kill a European outright. The same curious selection has doubtless taken place in some of our older New England towns where the native can drink the well-water with impunity while the stranger is affected at once.

In no other part of the world, unless it be in Russia, can such depths of filthiness be found as in the cities of China. Mr. Arthur H. Smith, in his interesting work entitled "*Chinese Characteristics*," says that, "No matter how long one has lived in China, he remains in a condition of mental suspense, unable to decide that most interesting question, so often raised, Which is the filthiest city in the Empire? . . . The traveller thinks he has found the worst Chinese city when he has inspected Foo-Chow, he is certain of it when he visits Ning-Po, and doubly sure on arriving at Tien-Tsin, yet after all it will not be strange if he heartily recants when he reviews with candor and impartiality the claims of Pekin!"

. . . . . .

The curious custom of compressing the feet of women, thus in a way rendering them cripples for life, is always alluded to in books on China. In the Peabody Museum of Salem are a few casts of this peculiar deformation made by the late Dr. G. O. Rogers, formerly of Hong-Kong. By the accompanying figure of one of these casts it will be seen that the four smaller toes are made to partially bend under the big toe and that the heel is also brought forward. This is accomplished by tight bandaging and usually begins as soon as the child is able to walk. According to Williams (see "*The Middle Kingdom*," Vol. II, p. 38) this practice is not confined to the higher classes; on the contrary, all classes of society, even the poorest, strive to be in fashion. The Tartars, though becoming Chinese in most matters, have had the good sense to let their women's feet develop normally. As to the origin of this savage custom Dr. Williams says, "A difference of opinion exists respecting its origin, some accounts stating that it arose from a desire to pattern the club feet of a popular Empress, others that it gradually came into use from the great admiration and attempt to imitate delicate feet, and others that it was imposed by the men to keep their wives from gadding; the most probable accounts do not place its origin further back than A. D. 950. . . . The appearance of the deformed member when uncovered is shocking, crushed out of all proportion and beauty and covered with a wrinkled and lifeless skin like that of a washwoman's hands daily immersed in soap-suds."



Plaster Cast of Compressed Foot.

. . . . . .

I was much interested in the archery methods of the Chinese, and an assistant in the school, a Manchu, illustrated their way of releasing an arrow from a bow, and also the manner of stringing a bow. The attitude of the hand in pulling the string differs greatly in different races. The Mongolian draws the string back with his thumb, the forefinger being bent over the end to strengthen the hold and the arrow being held in the crotch made by the junction of the forefinger and thumb. In this method a ring is worn on the thumb to engage the string and to prevent the thumb from being lacerated. That this method is very ancient is seen in the frequent allusions to the subject in the Chinese classics. In the "*Shi King*," or book of ancient Chinese poetry (translation of Legge), the thumb-ring is called a thimble and also a *pan chi*, or finger regulator: "With archer's thimble at his girdle hung," and, again, "Each right thumb wore the metal guard." The Mediterranean nations draw the string with the tips of the first three fingers, holding the arrow between the tips of the first and second fingers. The very lowest savage races pull the string by holding on to the arrow with the thumb and forefinger; a little more advanced savage assumes this attitude supplemented by bringing the second and third finger on the string and thus getting a stronger pull. I have dealt with this subject more fully elsewhere.[1]

Stringing a Bow.

The stringing of the bow is somewhat peculiar. The bow when unstrung turns back upon itself and is so short when in this state that it occupies but little room and may be carried in a convenient case. In stringing the bow the archer places one end upon his left knee, the bow passing under the right leg, then by pulling up the right end of the bow he can slip the loop of the string into the nock; or, the bow is bent over the knee as in the attitude of breaking a stick and an associate slips the loop into the nock. Great care is taken of the bow and a box is contrived for it in which charcoal is burned to preserve the bow in a perfectly dry condition.

EDWARD S. MORSE.

NOTES AND CLIPPINGS

MYSTERIOUS FIRES IN TALL BUILDINGS. — A recent fire in one of the tall office-buildings in Chicago developed a feature which is worthy of consideration on the part of fire-department officials in the larger cities. Although in the case referred to not much damage was done it was noticed that the flames went up the elevator-shafts with extraordinary rapidity, considering that in this particular building there was nothing for them on which to feed. When an investigation was made it was found that the steam-pipes, instead of being covered with asbestos, as the law demands, had been covered with some inflammable material. There had been one thin layer of asbestos paper, then a thick layer of felt and, finally, a canvas covering. When a match was put to the felt it burned like tinder. This discovery explained at once several mysteriously rapid fires in "fireproof" buildings, and a thorough investigation of pipe-coverings all over the city is to be made. Possibly, it would not be a bad plan to have a similar investigation made in New York and other large cities where lofty "fireproof" buildings exist. — *Metal Worker.*

THE CUMBERLAND ROAD. — The most remarkable highway built in the United States early in the nineteenth century was the so-called Cumberland Road, which was to extend from Cumberland, Md., through southwestern Pennsylvania, over the Alleghany Mountains to the Ohio at Wheeling, W. Va., and then on to St. Louis. It was so well constructed that it is a good road to-day. Henry Clay was its projector and chief supporter, and his services in its behalf are commemorated by a monument near Wheeling. We are told by letters written at that period that "there were sometimes twenty gayly painted four-horse coaches each way daily. The cattle and sheep were never out of sight, and canvas-covered wagons were drawn by six to twelve horses." On this great road, which eventually passed into the hands of the States through which it runs, the Government expended no less a sum than $7,000,000. Within a mile of it on either side the country was a wilderness, but on the highway itself the traffic was as dense as in the main streets of a large town. Ten miles an hour was the usual speed for coaches. From Baltimore to Wheeling ran lines of freight-wagons, which carried ten tons, drawn by twelve horses and with wheels 10 feet in diameter. — *Pearson's Magazine.*

SUBMARINE ROMAN REMAINS OF THE ITALIAN LITTORAL. — The British Consul at Naples remarks in his report for the past year that it is strange that, in spite of all the interest taken in southern Italy, and especially in the neighborhood of Naples, in archæology and exploration, no definite chart has ever been made of the important Roman remains beneath the sea, which stretch almost without interruption from Naples to Baia. It has been left to the British Association to undertake this task, and under its direction Mr. T. R. Günther, of Magdalen College, Oxford, has been engaged for some months in making a detailed survey of the Roman structures beneath the sea. From his notes it appears that the sea-level has risen about 20 feet since the era of their construction, and has covered many villas and piers, and probably also a road, which seems to have existed along the coast of Posilipo. Mr. Günther's survey will be of great practical value, apart from its scientific interest, because many boats run upon those old foundations annually, and only last year a steam-vessel of the Italian navy struck on one of them. This danger, however, is chiefly to pleasure-boats, and owners of yachts need to be especially careful when running along the coast in steam-launches. No less than three of these crafts have had narrow escapes in recent years. A careful record of the tides has been kept for some time, observations being made several times a day. The figures show the rise and fall to be greater than has been generally supposed, and also that the level of the Mediterranean is less influenced by the action of the wind than has been supposed by some observers. — *N. Y. Evening Post.*

AN ELECTRIC-HEATING DEVICE. — A system of heating houses and cars which combines the hot-water and electrical systems has been devised by a New Haven inventor. It is claimed to represent high efficiency and to give a uniform and most pleasant heat. The heater itself is made up of but few parts and is yet durable and inexpensive. It is composed of castings which form the connecting-heads and circulating-flue or water-chambers, around which are placed the electric-coils of high resistance. The latter are perfectly insulated by lava and specially prepared cement. The heads of the castings are made to receive iron plates, which are held in place by screws, and form a casting around the coils. The heat is controlled by a switch made to use in connection with this heater, and with its use the current is reduced without the aid of any external resistance, thereby keeping all the heat within the heating-apparatus. In the application of this system the electric water-heater is placed in the cellar in place of the ordinary coal-burner, the rest of the plant being the same as with the ordinary water-heating installation. The controlling switch may be located in any part of the house that may be desired, from which point the temperature of the entire structure may be regulated. The convenience of such a system will be apparent to any one. There is no handling of fuel or ashes, and there is also the advantage of instant adjustment. The principle has been applied to the radiator with an expansion tank and pig and circulating-pipes, thus forming a portable electric-heating system with a flexible-cord connection with the electric-light bracket. — *Boston Transcript.*

PRICE OF LUMBER LIKELY TO RISE. — John S. Gildersleeve, of Cleveland, who had been one of the group discussing the meat situation, said recently: "Perhaps the same complaint will be made when the price of lumber goes up, as I am told that it will do before very long. The prices now prevailing are said to be in all probability the lowest of the year. I was talking to-day with a New York lumber-dealer who cuts each year 30,000,000 feet of lumber in the northern sections of the East. He says that, because of the peculiar conditions this winter, the early thawing of the snow and the heavy rains, which washed out the logging roads, most of this winter's cut of timber will have to lie in the woods until another season, and where he should have now, with his reserve, 40,000,000 feet of timber in the ways, he has but 15,000,000. This will cause what might by some people be unjustly called a corner. No more wood can be got out into the market, and he can make a higher price on his lumber, but it is a natural, not an artificial, corner. In order to supply his trade and meet the regular orders that are sure to come in, he will not sell out his 15,000,000 feet at once, as he could do, but will make his own price, and sell it as his orders come in. No one can justly blame him for doing this." — *N. Y. Tribune, April* 20.

"LLOYD'S REGISTER'S" NEW BUILDING. — "Lloyd's Register," the new building just erected at 71 Fenchurch Street, is beyond question the most gorgeous of the many palaces of commerce in the city of London. Its total cost, £100,000, is perhaps not particularly striking until its comparatively small size is remembered. In comparison with its size, the new building is perhaps the most costly in the Kingdom. "Lloyd's Register" must not be confused with "Lloyd's," the society of underwriters. The Register exists for classifying the ships of all nations. Here it is decided in which class to place a new vessel for insurance purposes, and it is in the power of the committee of this institution to award or withhold their highest diploma of "A1 at Lloyd's." Constructed of the finest Portland-stone, the building is a thing of great architectural beauty from the outside. The carvings on the porch and the bronzes between the pillars are by Mr. Frampton, R. A., and are executed in his best style. The weather "cocks" are two little ships of copper-gilt, one a modern liner and the other an ancient fifteenth-century sailing-boat. Valuable marbles, inlaid woods, mother-of-pearl, and even jewels have been utilized in the decoration of the interior. Mr. T. E. Colcutt, the architect, gave the writer some detail of his work, which in beauty of design and wealth of decoration is indeed a masterpiece. "Quite the costliest part of the building," said Mr. Colcutt, "is the frieze of Mr. Lynn Jenkins representing a procession of mediæval ships. The vessels are of bronze, the sky of mother-of-pearl, and the figures of bronze with ornaments of real sapphires. The supporting pillars are of polished marble. The mantelpiece is exceptionally beautiful carved marble. The fire-dogs, of old Italian work, stand 6 feet high, and are worth £500. Even the clerks' office is more suggestive of a palace than a business-house, for it is lined with marble, and the electric-light fittings are of beaten copper. The story of how the new luxurious building came into existence is rather interesting. For classifying ships "Lloyd's Register" charges certain fees. The income more than covered the expenses, and a large reserve-fund accumulated. For the disposal of this sum, outside the defraying of expenses, there was apparently no provision, so, finally, it was decided to expend it upon a building that should do credit to London and take a high place among the commercial palaces of the world. — *London Mail.*

NOTES AND CLIPPINGS. 72

THE appeal of Mr. Edward Atkinson for funds to establish an insurance engineering experiment station seems to have met with an immediate and liberal response from the manufacturers who, under his wise guidance, have come to appreciate, perhaps better than any one else, the incalculable value of intelligent precautions against fire; and the Experiment Station has already been organized, and will begin its work with such resources as are now available, under the charge of Prof. Charles L. Norton, of the Massachusetts Institute of Technology. Architects will be glad to hear that the first problems to be solved will be those relating to fireproof construction, particularly in respect to the corrosion of metal skeletons encased in masonry; and we hope that the managing officials, all of whom are officers of mill mutual insurance companies, will forget the usual underwriter's scorn for architects long enough to invite from some of the latter suggestions as to the varieties of construction to be tested. For example, architects understand, much better than mill-engineers or insurance-men, the departures from the standard construction which really constitute the greatest danger in modern steel-frame buildings. The steel skeleton, conscientiously buried under a foot of solid, well tied and well grouted masonry, can, so far as our present knowledge indicates, be safely left, at least for a few months, while the Experiment Station is studying the present, and probable future, condition of those "wonderful" structures, run up in a few weeks, with bolted joints, and cased with four inches of loosely-fitting brickwork, in which so many millions of dollars have been invested within the past ten years. One of the most recent innovations in these "wonderful" buildings is said to be to lay the wooden floors without any sleepers or nailing-strips whatever, driving the flooring-nails simply into the cinder concrete. An investigation into the length of time that floors laid in this way will stay in place would be of interest to owners, as well as to architects. The action of cinder concrete, made in the usual manner, and of the plaster-of-Paris beam-filling, used in some varieties of fireproof-construction, and of acid hard plasters, on the steel structure which they are supposed to protect, is also a matter of vital importance. It may be observed that the use of plaster-of-Paris for repairing, and filling-out deficiencies, in terra-cotta work is not wholly unknown, and, perhaps, the first portions of most steel structures to show signs of corrosion will be found to be the portions under the windows, where the water soaking through stone sills, or through the joints of terra-cotta sills, keeps the masonry generally moist, even if it does not carry with it acid substances in solution.

SPEAKING of the difficulty which architects find in determining technical questions of this kind for themselves, and the bewilderment into which they are thrown if they attempt to gather instruction from the "expert tests," lectures, "papers" and so on, by eminent professors, engineers and others, accounts of which reach them by nearly every mail, it might be well to call the attention of the new Experiment Station to the peculiarities of certain bricks, and their possible influence upon structural steel embedded in them. Architects were informed, not long ago, that such steel rusted only under the influence of carbonic acid, and that, when surrounded, even at a certain distance, by masonry, the cement in the masonry captured all prowling particles of carbonic acid, so that the steel could never be attacked. Now, even in steel-frame structures, and, perhaps, particularly in them, the bricks used are often seen to be covered with a white efflorescence. This efflorescence varies in composition, but, as chemists tell us, it often consists, wholly or in part, of sulphate of magnesia, and its presence is attributed to the combination of sulphuric acid, derived from the sulphur in the coal used for burning the bricks, with something in the clay of the bricks, or in the cement used for laying them. Now, sulphate of magnesia is an acid salt, capable of corroding iron rapidly, and the simple-minded architect, when he sees a sheet of what he supposes to be this substance on the outside of a four-inch brick wall, the inside of which is in contact with a steel frame, may be forgiven for wondering whether the metal within is not experiencing some effect, and for asking himself why the masonry which catches carbonic acid so cleverly should let sulphuric acid escape in such quantities. Naturally, we are far from presuming to answer these questions, but the founders of the Experiment Station may be assured that no one will study the results obtained by it with greater interest and gratitude than the architects.

THOSE architects who enter competitions in which they bind themselves, if their design is selected, to furnish security that the contract price will not exceed a certain sum, and who imagine that this is only an innocent formality, will do well to take warning from what is now going on in Massachusetts. One of the most prosperous cities in this Commonwealth proposes to build a high-school, and has issued a programme of competition in which, among other things, it is stipulated that the cost of execution shall not be more than one hundred and eighty thousand dollars, and that the successful competitor shall give bonds "in a reasonable amount" that this limit shall not be exceeded. One of the architects invited to compete, having, presumably, something to lose, and entertaining a wholesome distrust of "mere forms" in the shape of bonds, asked the chairman of the committee in charge of the matter certain questions in regard to the bonds which would be required, and received replies in writing. To the first question, whether, in case the contractor should fail before the expiration of his contract, and it should become necessary to make new contracts, at an increased price, for the completion of the building, the architect's bond would be forfeited, the answer was "Yes." To the second question, whether, in case prices of material or labor should advance during the period between the selection and the letting of the contracts, so as to make it impossible to contract for the building for the specified sum, the architect's bond would be forfeited, the same answer was returned. The third question was whether the architect, in case the lowest bid on the completed plans and specifications exceeded the limit, would be discharged without pay, or would be directed to modify the drawings and specifications to reduce the cost to the necessary extent; and the reply to this was that he would be discharged without pay.

THE programme of competition, in this case, is quite free from the odor of cheating rascality with which so many documents of the kind reek, and the committee seem really to wish to get the best building that they can for their money, yet a proceeding less calculated to bring about that result could hardly have been devised. No provision is made for expert advice in making a selection, although, without such advice, the committee is as likely to choose the worst design as the best. We have known a very intelligent committee to select a plan for a high-school in which the main entrance-hall was, practically, without light or air, and it was not until their expert advisers pointed out to them the absence of windows that they regretfully abandoned their choice; and the amount of money which is spent in altering buildings, particularly school-houses, to correct defects in plan which an expert would have seen at

Entered at the Post-Office at Boston as second-class matter

once is something startling. The committee in the present case, by assuming the selection, not only make it tolerably certain that, if they choose and carry out any plan, they will either have to alter their building later, or impose upon the children who are to use it the annoyances and fatigues which are the result of unskilful planning, and which, multiplied by the number of people who suffer from them, constitute a heavy burden on the community, but, by that circumstance alone, they keep capable and skilful architects from accepting their invitation. In England, and in the larger cities of this country, it is considered that an architect who enters a competition which is not to be judged by an expert does so expecting to win, if at all, by unfair means; and those who depend upon the merit of their work for recognition will not compete with him. Moreover, as if to make doubly sure that no respectable architect will enter the contest, the committee imposes on competitors a money forfeit which is, for an architect, pure gambling, with loaded dice in his adversary's hands. An architect who has entrusted his property in this way to a building-committee can be robbed of it at the pleasure of the committee, by collusion between contractors, or by any one of a variety of accidents which he is powerless to prevent. It is true that the pretexts on which his money would be confiscated would rarely bear the test of a judgment of court, but it must be remembered that possession is nine points of the law, and the mangled remains of his savings which he would receive after two or three years' fighting would not make up for the loss of time involved in the contest.

ARCHITECTS, who often have to advise in regard to the grading and planting around the houses which they design, may find instruction in the report of interviews with the officials of the New York and Brooklyn parks. Some one, observing that signs were scattered plentifully around the New York Central Park, warning people to keep off the grass, while, in Prospect Park, in Brooklyn, there were no signs, and visitors were permitted to walk about freely, made inquiries, and found that, while walking over the sod in the Central Park was destructive to it, that in Brooklyn would survive almost any treatment. Application to Mr. Samuel Parsons, the landscape architect of the New York parks, brought out the interesting information that the difference was due to the thinness of the soil in the Central Park as compared with that in Prospect Park. According to Mr. Parsons, the vegetation in the Central Park is in a dying condition, for want of suitable and sufficient soil, and nothing but the greatest care and vigilant protection against ill-treatment can keep it in tolerably presentable condition. The site of Central Park was, originally, a rocky tract, with barely enough grass growing in the crevices of the ledges to feed the goats pastured there. Naturally, the goats made short work of any young trees that might endeavor to grow in the richer spots, and the place, although it presented a picturesqueness which is still one of its most attractive features, was far from suggesting luxuriant vegetation. To secure anything like shrubbery and grass, soil had to be brought from a distance, and spread over the rocks and gravel. This soil has supported the vegetation of the park until now. Unfortunately, the cost of soil made it seem necessary, when the park was first laid out, to limit the quantity used, and it was spread out too thinly. Now, in Mr. Parsons's opinion, the trees and grass, if they are to be preserved, must be supplied with fresh soil, to an average depth of two feet. The cost of this, including that of spreading and replanting, would be a million and a half, and even now, when the Central Park has become the most valued ornament of the richest city but one in the world, it is impossible to get such a sum appropriated for the purpose. Some years hence, when the shrubs are dead, the trees reduced to unsightly stumps, and the grass-plots to patches of alternate brown and green, public opinion will demand the necessary expenditure, but this must then be much greater, and young plants and trees must be set out to take the places of the old ones which no treatment can save.

A MODEST attempt has been made at a beginning of amelioration of the present tariff laws of the United States in regard to works of art, by the introduction of a bill in the House of Representatives, by Mr. Lovering, of Massachusetts, providing that statues, paintings, drawings, engravings and etchings may enter this country free of duty, if they were executed more than fifty years before the date of importation. This reservation, it will be seen, still protects the tin-can artists of the United States against the competition of the Raphaels and Michael Angelos of the effete countries of Europe, for the reason that, as tin-cans were little known fifty years ago, the "pauper labor" of the artists of the Renaissance was devoted almost exclusively to other objects; and it seems as if the most inveterate champions of American "infant industries" could find nothing to object to in the bill. Whether it will be passed is, however, another question. The defenders of the protective system appear to have determined not to permit any change, however innocent or desirable, in the present tariff. The consequence of this attitude will be, as it seems to us, that the people who, in constantly increasing numbers, are aggrieved or injured by the injustices and anomalies of the tariff, finding that it cannot be modified, will have no alternative but to join in destroying it, with the most deplorable effect upon business of all kinds.

IT is welcome news that New York in the sculptural adornment of its public and semi-public buildings seems likely to differentiate itself permanently from such cities as Berlin and Vienna, where the unthinking facility of architectural sculptors has wrought such deplorable results upon and over façades that have in them at least the elements of architectural serenity. Almost any sculptural treatment would be better than the allegorical imaginings of the German *Bildhauer* as they sprawl or crawl over the broad surfaces or contort themselves so as to crowd into the odd corners of what are really fairly decent façades. Up to the last decade, or until since the Chicago Fair, architects hardly dreamed of employing more than capitals and ornamented string-courses in their buildings, though the far-seeing ones had begun before that to build into their structures the rough blocks in which might perchance be hewn a bit of sculpture in high-relief or in the round — at some time dimly perceptible. Almost the first pieces of real sculpture applied to an American building in a structural sense are Daniel C. French's fine marble groups over the main entrance to the Boston Post-office — too high up to be fairly seen, but even there telling and certainly good. It is matter for gratulation that he is to make a statue of De Witt Clinton for the New York Chamber of Commerce, while Philip Martiny is to model statues of Alexander Hamilton and John Jay for the same building. These figures, following the example of those modelled by J. Massey Rhind for the Exchange Court Building, would seem to establish a fashion of utilizing American notables for decorative purposes which may spread, and with happy artistic effect, so long as the garments of to-day are not too much forced on the attention by the sculptor.

THE Municipal Art Society of New York announces its competition for designs for an electrolier, to be placed on the "island" with which the municipality proposes to divide the traffic at the intersection of Fifth Avenue and Twenty-third Street. The island will not exceed in size eight by twenty feet, so that the electrolier must not be too large to be comfortably accommodated on a plot of these dimensions; and it must be comparatively simple, the limit of cost being fixed at fifteen hundred dollars. Designs or models must be delivered, under motto, to the Secretary of the Municipal Art Society, at the building of the Architectural League, West Fifty-seventh Street, on or before six o'clock in the evening of June 11. They must be accompanied by a brief specification, and by an envelope, sealed with wax, bearing on the outside the competitor's motto, and having his name and address inside. The jury consists of ten artists and architects, and five laymen, and the author of the design placed first will be employed to furnish full-size drawings, and such modelled details as may be necessary for the execution of the work, receiving for these services a fee of five hundred dollars. The second prize will be one hundred dollars, and the third fifty dollars.

THE Pratt Institute, in Brooklyn, N. Y., has developed with a rapidity which shows conclusively that it has supplied a want widely felt. In 1887, it had twelve students; in 1901, it had more than three thousand. With the rest, and perhaps even more than the rest, the Department of Fine-Arts has increased in importance, until, from a single studio, it now includes thirty. The facilities available for the necessary study have led the Trustees to establish a two-years' course in architecture, designed more particularly to train students for efficient and responsible work as assistants in architect's offices. The programme indicates that this object is attained, so far as is possible in a two-years' course.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — VII.

THE columns in the modern building, and especially in the construction known as the skeleton type, are the most important members or elements in the structure. They may be either of cast-iron or structural steel. When of the former they are usually of a hollow cylindrical or rectangular section, when of the latter, it is customary to build up the section of rolled shapes and plates securely riveted together throughout their length. There is much debate between engineers regarding the relative efficacy of cast-iron and structural-steel columns. It is a fallacy to suppose that cast-iron behaves badly in case of fire, and that columns of this material upon being suddenly cooled are subject to fracture by unequal expansion. A systematic examination of the results of fires in buildings shows that cast-iron columns stand remarkably well — in fact, have fire-resisting qualities superior to columns of structural steel. The principal disadvantage in the use of cast-iron columns consists in the fact that it is difficult to make rigid connections between the columns of the several tiers, and cases have occurred where tall buildings that depended upon the rigidity of the beam-connections and the connections of one column to another for their lateral strength have been thrown out of plumb by the horizontal wind-pressure. Such a failure was particularly noticeable in a ten-story building erected in New York, which when partially completed was found, after a heavy storm, to be about 10 inches out of the vertical. By the use of the numerous rolled shapes a multiplicity of structural-steel columns have been designed. The principal ones have become standard and are known as the angle column, the Z-bar, the box, the Grey and the Larimer. The usual sections of these columns are shown in Figure 42.

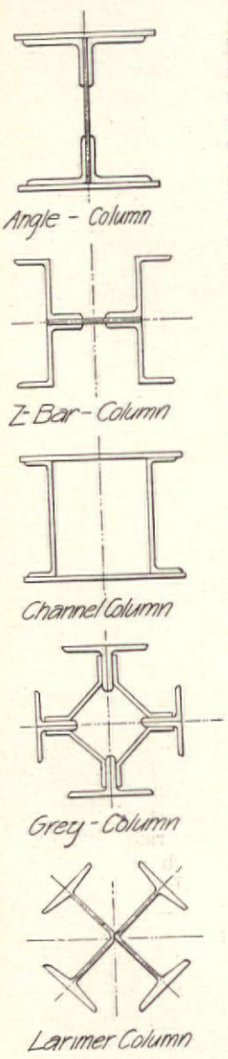

Fig. 42.

Columns under ten diameters in length are liable to fail by crushing, while columns where the ratio between the diameter and the length is greater than this are liable to fail by lateral flexture and crushing at the ends. The strength of the column depends, therefore, upon its length and also upon the distribution of the metal in its section, for where columns have the same area the one in which the metal is distributed farthest from the centre will offer the greatest resistance. The distribution of the metal in the column-section is determined by the radius-of-gyration of the section. If all the metal in a column-section were assembled at a distance from the centre equal to the radius-of-gyration, the column would offer the same resistance to flexure as if the material were distributed throughout the cross-section.

Not only does the strength of a column depend upon its length and radius-of-gyration, but it also depends upon the shape of the ends and the manner in which they are secured. Cast-iron columns in buildings are provided with flat ends only, and one formula will cover all cases which may arise. The formulas for hollow, round and rectangular cast-iron columns with square ends are based upon Gordon's formulas. These formulas may be stated as follows: —

Rule I. — The safe load in tons per square inch that a hollow cylindrical cast-iron column with square ends will support is equal to the quotient obtained by dividing 5 by the sum of 1 and the quotient obtained by dividing the square of the length of the column in inches by 800 times the square of the outside diameter in inches.

Rule II. — The safe load in tons per square inch of section for hollow square cast-iron columns with square ends is equal to the quotient obtained by dividing 5 by the sum of 1 and the quotient of the length of the column in inches, squared, divided by 1,067 times the least diameter squared.

[1] Continued from No. 1371, page 6.

The results of both of these rules are in tons of 2,000 pounds, and provide for a factor-of-safety of 8, when a unit ultimate compressive strength of 80,000 pounds is considered. The rules may be expressed by the following formulas: —

For hollow cyclindrical columns

$$s = \frac{5}{1 + \frac{l^2}{800\,D^2}}$$

For hollow square columns

$$s = \frac{5}{1 + \frac{l^2}{1{,}067\,D^2}}$$

in which s equals the safe unit compressive stress in tons, l equals the length of the columns in inches, and D equals the outside diameter, or the length of the least side in inches.

Where the ultimate strength of cast-iron columns in pounds per square inch of cross-section is desired the following formulas may be used instead of the above: —

For hollow cylindrical columns

$$s = \frac{80{,}000}{1 + \frac{(12\,L)^2}{800\,D^2}}$$

For hollow rectangular columns

$$s = \frac{80{,}000}{1 + \frac{(12\,L)^2}{1{,}067\,D^2}}$$

In these formulas s equals the ultimate unit compressive strength in pounds, L equals the length of the column in feet, and D, as before, equals the outside diameter, or the length of the least side in inches. In application of the above formulas assume the following problem: —

Example. — Required, the safe load for a hollow round cast-iron column 18 feet long and 12 inches in outside diameter, provided the metal is 1 inch thick, and a factor of safety of 8 is desired.

Solution. — The sectional area of the column is equal to $.7854\,D^2 - .7854\,d^2$, or, since D is the outside diameter of the column, and d is the inside diameter of the column, the area equals

$(.7854 \times 12 \times 12) - (.7854 \times 10 \times 10) = 34.55$ square inches.

Having obtained the sectional area, the safe unit compressive stress in tons may be determined by substituting in the formula

$$s = \frac{5}{1 + \frac{l^2}{800\,D^2}}$$

which then becomes: —

$$s = \frac{5}{1 + \frac{216 \times 216}{800 \times 12 \times 12}} = 3.57 \text{ tons.}$$

By multiplying this value by the area, 34.55 square inches, as previously obtained, the entire bearing-capacity of the column is found to be 123.34 tons.

For convenience in determining the safe load any cast-iron column will support, without working out the lengthy formulas described, the following tables have been evolved: these tables

STRENGTH OF HOLLOW CYLINDRICAL AND HOLLOW SQUARE CAST-IRON COLUMNS.

$\frac{L}{D}$	Ultimate unit compressive stress.		$\frac{L}{D}$	Ultimate unit compressive stress.	
	Cylindrical.	Rectangular.		Cylindrical.	Rectangular.
1.0	67,800	70,400	2.5	37,600	43,300
1.1	65,600	68,700	2.6	36,000	41,800
1.2	63,500	66,900	2.7	34,500	40,300
1.3	61,300	65,100	2.8	33,100	38,800
1.4	59,100	63,200	2.9	31,800	37,400
1.5	56,900	61,300	3.0	30,500	36,100
1.6	54,700	59,400	3.1	29,300	34,800
1.7	52,600	57,500	3.2	28,100	33,500
1.8	50,500	55,600	3.3	27,000	32,300
1.9	48,400	53,700	3.4	25,900	31,200
2.0	46,500	51,900	3.5	24,900	30,100
2.1	44,500	50,100	3.6	24,000	29,100
2.2	42,700	48,300	3.7	23,000	28,000
2.3	40,900	46,600	3.8	22,200	27,100
2.4	39,200	45,000	3.9	21,400	26,200

NOTE. — The value of L is in feet, while the value of D is in inches.

gives the ultimate strength in pounds per square inch of section for columns having different values of $\frac{L}{D}$, that is, the ratio between the length of the column in feet and the diameter in inches. In order to use this table, first fix upon the factor of safety, and then determine the sectional area of the column. Having found the ratio of $\frac{L}{D}$ for the column under consideration, divide the value in the table by the factor of safety, and multiply this quotient by the sect onal area of the column. For instance, assume that a column is 16 feet in length and 10 inches in diameter. The ratio of $\frac{L}{D}$ is 1.6, and from the table the ultimate strength in pounds per square inch for a hollow cylindrical column having this proportion between the diameter and length is 54,700 pounds. If a factor of safety of 6 is required, the safe bearing-value for each square inch of section will equal 9,116, provided the column is $\frac{3}{4}$-inch metal, this sectional area will equal 21.7948 square inches, and the working-strength of the column will be 9,116 × 21.79, or 198,637 pounds.

The formulas commonly used in figuring the strength of structural-steel columns are the Gordon formula and the straight-line formulas. The Gordon formula is the most complicated, and has been substituted by the straight-line formulas, which appear to give results more nearly agreeing with tests made upon full-sized column-sections.

The columns, as previously stated, may be either hinged flat on the ends or fixed. Hinged columns are those which are connected in a structure by pins, and only occur in bridge and heavy truss work. Flat-ended columns occur frequently in building-construction, in fact are usual where the columns continue from floor to floor, the base of one resting upon the cap of the other.

Columns with fixed ends are principally struts that occur in riveted frame structures, and it is not usual to consider columns where the floor-beams are bolted or riveted to brackets as having fixed ends. The Gordon formulas for the different columns are as follows: —

Hinged ends

$$s = \frac{s_1}{1 + \left(\frac{l^2}{18{,}000\ R^2}\right)}$$

Square ends

$$s = \frac{s_1}{1 + \left(\frac{l^2}{24{,}000\ R^2}\right)}$$

Fixed ends

$$s = \frac{s_1}{1 + \left(\frac{l^2}{36{,}000\ R^2}\right)}$$

In these formulas s equals the ultimate unit compressive stress upon the column-section; s_1 equals the ultimate unit compressive stress of the material (in structural-steel columns generally assumed at from 50,000 to 60,000 pounds), l equals the length of the column in inches, and R equals the least radius-of-gyration, which may be determined by means described in connection with article which appeared in the January 18th issue of the *American Architect*. The results obtained by these formulas will give approximately the ultimate supporting strength of any structural-steel column, per square inch of section, and the value should be divided by the factor of safety,

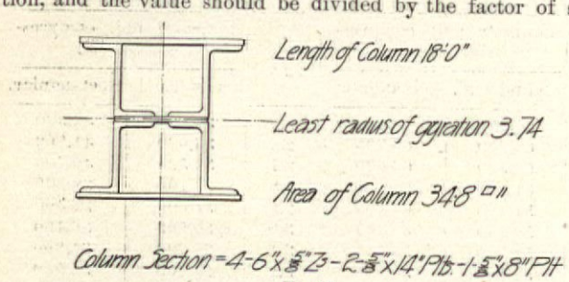

Fig. 43.

from 3 to 5, though commonly taken at about 4. In application of the above formula, assume the following problem: —

Example. — The Z-bar column shown in Figure 43 has a least radius-of-gyration of 3.74 and a length of 18 feet; provided medium steel, with an ultimate compressive strength of 60,000 pounds, is used, what will be the safe load the column will support? The ends of the column are flat.

Solution. — The safe unit compressive strength of the column-section is equal to s, or

$$\frac{60{,}000}{1 + \frac{216 \times 216}{24{,}000 \times 3.74}} = 39{,}474 \text{ pounds.}$$

If a factor of safety of 4 is used the allowable unit stress will equal 39,474 ÷ 4 = 9,868. Since the area of the column in

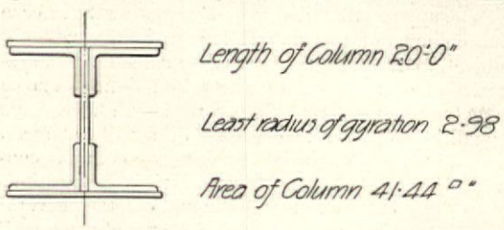

Fig. 44.

Figure 43 equals 34.8 square inches, the allowable working stress on the column will equal 9,868 × 34.8 = 343,406 pounds, answer.

The straight-line formulas (so called because when plotted they will give a straight line) are more convenient and more accurate than the Gordon formulas just given. These formulas are for columns whose lengths are between 50 and 150 radii-of-gyration. The formulas for the several types of columns and for medium and soft steel are as follows: —

MEDIUM STEEL.

Hinged or pin-connected ends, $s = 60{,}000 - 260\frac{l}{R}$

Square or flat ends..... $s = 60{,}000 - 230\frac{l}{R}$

Fixed ends..... $s = 60{,}000 - 210\frac{l}{R}$

SOFT STEEL.

Hinged or pin-connected ends, $s = 54{,}000 - 225\frac{l}{R}$

Square or flat ends..... $s = 54{,}000 - 200\frac{l}{R}$

Fixed ends..... $s = 54{,}000 - 185\frac{l}{R}$

In these formulas l equals the length of the column and R the radius-of-gyration, both values being in inches. In application of the above formulas, assume the following problem: —

Example. — Required, the safe bearing-strength of the angle column shown in Figure 44, when its length is 20 feet, its sectional area 41.44 square inches, and its least radius-of-gyration 2.98, provided the column is built of medium steel, has square or flat ends, and is to have a factor of safety of 5.

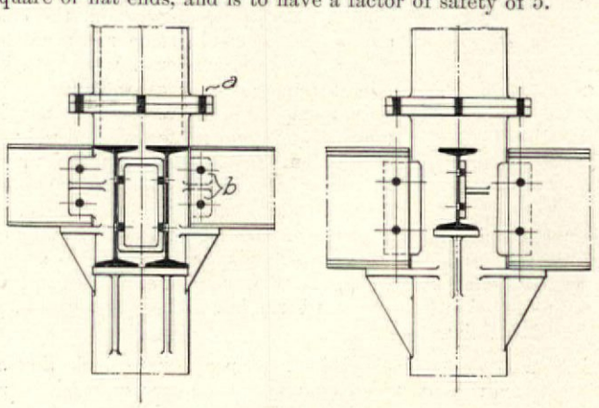

Fig. 45.

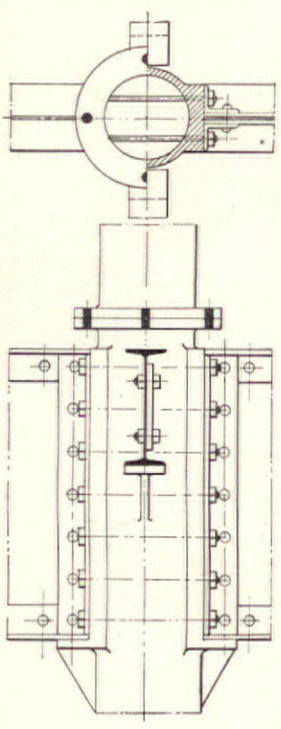
Solution. — From the example $l = 240$ and $R = 2.98$; then by substitution in the formula $s = 60{,}000 - 230 \times \frac{240}{2.98}$, or 41,485 pounds per square inch; this divided by 5 gives 8,297 pounds, the allowable compressive stress per inch of area upon the column-section; from the problem the area of the column is 41.44; therefore, the allowable bearing-strength of the column equals 8,297 pounds × 41.44, or 343,827.

Considerable study can well be put upon the design of cast-iron columns, and especially should careful consideration be given to the brackets and connections for securing the floor-girders to the columns. Where the column is cylindrical the general design shown in Figure 45 is usually employed for the supporting brackets and connecting webs of the floor-system.



The upper column is secured to the lower by means of bolts through the flanges, as at *a*, and care should be taken to have these bolts a snug fit, for upon them depends the alignment of the column, and, to a certain extent, its rigidity from floor to floor. Tests made upon brackets cast upon columns show that they usually fail by tearing out an adjacent section of the column shell. For this reason it is found advisable to thicken up the metal in the column shell around the brackets, and especially should large fillets be provided in all corners. The top and bottom surfaces of all cast-iron columns should be faced true, at right angles to the axis of the column, and all columns of a tier should be of uniform length. The holes in the connecting-webs, as at *b b*, are cored, usually $\frac{1}{8}$ inch larger in diameter than the bolt, while the best practice requires the holes drilled, as at *a a*, in the flanges.

Where a plate-girder forms one of the principals of a floor-system the construction shown in Figure 46 is usually employed. Such a connection is very rigid, and furnishes considerable lateral stiffness to the structure. The base of each column should be designed as shown in Figure 47. The bottom flange is usually made from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches in thickness. It is not advisable, however, to have it greatly thicker than the shell, for the mass of metal at this point causes undue shrinkage, and is likely to create initial strains. The webs are preferably placed upon the diagonal. The base of the column, as shown, may rest directly upon the capstone of the pier, but it is far preferable to provide a bearing-block of cast-iron, as designated in Figure 48. The advantage obtained by the use of these blocks consists in the fact that they can be erected upon the tops of the piers, and carefully aligned and levelled, forming a reliable and accurate means for setting the columns.

For protection against fire a column with a double shell is often employed, as shown in Figure 49. The interior column sustains the weight of the floor, while the exterior is merely a fireproof protection. This practice is not used to any great extent, as a fireproof covering of terra-cotta or concrete upon expanded-metal is considered fully as reliable, and far less expensive.

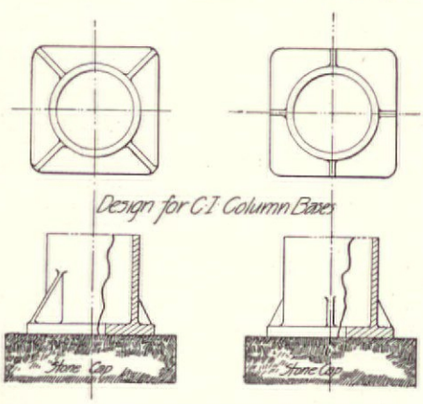


Fig. 47.

In inspecting cast-iron columns at the building it is often necessary to reject some, on account of the unequal thickness of the shell. Where the column is cast in a horizontal position the core is liable to drop, and the metal on one side of the column may be $\frac{3}{8}$ inch thick, while on the other it is $1\frac{1}{8}$ inches, when the uniform thickness of the column should have been $\frac{3}{4}$ inch. This unequal distribution of the metal is likely to cause the failure of the column by side flexure. Blow-holes and cold-shuts, when of sufficient size, will condemn a building column. Unscrupulous foundrymen sometimes cover up such defects with a filler and putty, or Babbitt metal, and such filling when under paint can only be detected with a knife or hammer. In order to determine whether the shell of the column is of uniform thickness $\frac{1}{8}$-inch holes should be drilled through the column on the diameter at right angles to the parting. Through these holes, by means of a piece of bent wire, the thickness on the two sides can readily be ascertained. The shaft of the column should be straight, not deviating more than $\frac{1}{4}$ inch or $\frac{3}{8}$ inch, and it is well for appearance to accept only such castings as are true to pattern, having sharp corners and smooth surfaces.

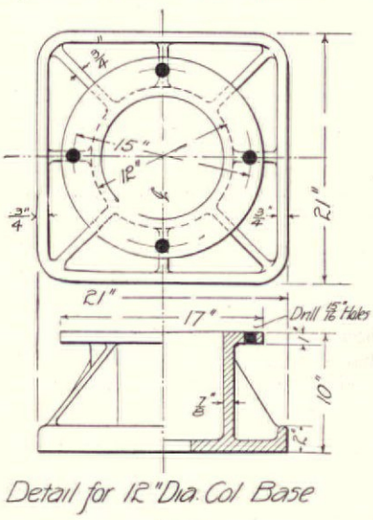

Fig. 48.

Columns in building-construction are often subjected to eccentric loading — that is, where the point of application of the load is without the centre of the column. Such a load exists in outside columns where the heavy weight of the wall on one side is not counterbalanced by the floor load. Provision must be made in the sectional area of the column to take care of this eccentric load. The eccentric load creates a bending-moment in the column, and the bending-moment is equal to the amount of the load multiplied by the distance of its line of action from the centre of the column.

For instance, in Figure 50 the amount of the load upon the bracket to one side of the column is 20,000 pounds, and the distance from its point of application to the centre of the column is 20 inches. In consequence, the bending-moment upon the column equals $20{,}000 \times 20 = 400{,}000$ inch-pounds. The bending-moment due to an eccentric load upon a column, then, is found by the formula $M = W l$, in which W equals the weight or load in pounds, and l the distance from the line of action of the load to the centre of the column. From a previous article it was found that M must equal M_1 — that is, the bending-moment must equal the resisting-moment. Since M_1 equals $\frac{s I}{c}$, $M = M_1 = \frac{s I}{c}$, in which s equals the safe unit fibre-stress, I the moment-of-inertia of the section, and c the least distance of the outside fibres of the section from the neutral axis. The radius of-gyration, or R, is always equal to the square root of $\frac{I}{A}$, or $R^2 = \frac{I}{A}$, in which A equals the entire area of the section. From this formula I must equal $R^2 A$, and the value $R^2 A$ must be substituted for the value of I in the formula $M = M_1 = \frac{s I}{c}$,

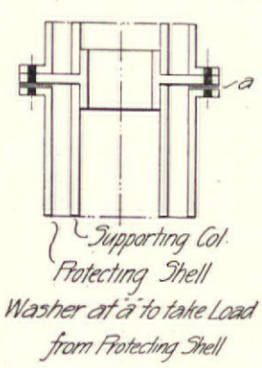

Fig. 49.

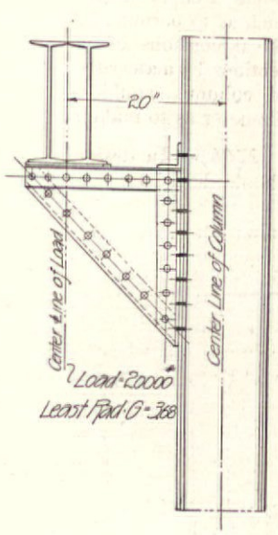

Fig. 50.

so that $M = \frac{s R^2 A}{c}$, or, by transposition, $A = \frac{M c}{s R^2}$. This latter formula gives the area that it is necessary to add to the section of any column in order to resist the bending-stress due to an eccentric load. Upon providing for this increase in area in the

column-section the radius-of-gyration should be carefully figured or determined, to see that it does not vary materially from the value of R^2 used in the formula for determining the additional area required.

In application of this formula, assume the following

Example. — Determine the additional area that it will be necessary to add to the column-section, subject to the conditions of loading described in Figure 50.

Solution. — The bending-moment, as previously explained, equals $W l$, or $M = 20{,}000 \times 20 = 400{,}000$ inch-pounds, and A equals by the formula $\frac{400{,}000 \times 6}{15{,}000 \times 3.68 \times 3.68} = 11.8$ square inches; this being the additional area required in the column-section in order to resist the bending-moment caused by the eccentric load. Provision can be made for this additional load by increasing the weight of the channels, or the thickness of the cover-plates.

Careful consideration should be given by the designer of skeleton-construction to what is the best type of column applicable to the work in hand, and, in deciding, the following points should be carefully reviewed: —

First. — Economy both as regards material and workmanship. The column should be as light as possible consistent with the work that it has to perform, though due regard should be paid to the possibility of corrosion and the ultimate weakening of the column from this effect. The column-section in which the radii-of-gyration upon the two axes are most nearly equal probably offers the most economical section. The riveting throughout the column should be arranged so that it can be readily done by power. The rolled sections should be selected with due regard to stock sizes of rolled shapes, so that no difficulty will be experienced in obtaining the material. Patented sections are subject to the disadvantage, when the supply is located at a distance from the point of erection, of being not readily obtainable, and prompt shipments not always possible.

Second. — The column-section is preferable that allows the floor beams or girders to be connected close to the centre of the column, for by this means dangerous eccentric loads are avoided, and the reactions of the girders or beams are transmitted directly to the centre of the column.

Third. — Simple construction at the connections is preferable. Bent or swaged plates of peculiar shape are objectionable, and, in designing the connection, rigidity in assembling the work should always be borne in mind.

Fourth. — Such a column-section should be designed that the reduction in the sectional area of the columns throughout the several tiers may readily be attained by reducing the sectional area of the rolled-steel shapes. The design should be such as to permit of this reduction without changing materially the dimensions of the column-sections. Should the column-sections be materially changed it is evident that the upper tier of columns would be of such light construction and small diameter as to make adequate beam-connections difficult.

Fifth. — In designing the column-section careful attention should be given to accessibility for inspection and painting. When the fireproofing is complete this consideration is of little importance, as the covering cannot generally be removed to inspect columns, and besides the fireproof covering tends to prevent the accumulation of moisture on the column, and hence lessens the liability of deterioration.

Further data with fegard to the design of structural-steel columns, their beam and girder connections and lateral bracing will be taken up in the next article. M. M. Sloan.

[To be continued.]

A FEW PARIS JOTTINGS.

PROBABLY the man is unknown who having a day, or even a few hours, in Paris *en route* for any place in Europe, or in any part of the wide world, does not find something new to amuse or instruct him. The mere streets are constantly changing, although the shops remain the same, with the same *articles de Paris*, the same photographs, the same colored frivolities. One part of Paris seems to vie with the other, — progress and conservative conventions glide on side by side, as in no other city. Only a year ago, the Exhibition buildings were disappearing, trams were regaining their normal ways, and the débris of the World's Fair was scarcely swept away. Now all is spick and span, and the city is once more a delightful specimen of what a city ought to be.

Many of the buildings of Paris are in bad taste and some are most atrociously ugly; but one and all are made decorative, in forming centres or vistas of streets and squares. There is no haphazard in Paris improvements. When the two new palaces were designed for the Retrospective and Beaux-Arts departments of the Exposition, they were placed on each side of the approach to the new bridge, the Alexandre III. The bridge started from the centre of the Place des Invalides, and the whole design was intended to form an architectural decoration leading up to Bruant's old hospital. It was a fine idea, and the result is beautiful; from the Champs Elysées one looks across the bridge and up the Place to the gilded dome. It is one of the finest vistas one can see anywhere.

The old rooms of the Louvre which used to contain drawings by the masters, faïence, glass and the Sauvageot Collection are now resplendent with painted ceilings, tapestried walls, rich damask curtains and old furniture — all from the Garde Meuble. Many of these treasures were in the Retrospective Exhibition of 1900. Boulle cabinets, the great *gaines* in Rouen-ware, some fire-dogs by Gouthière (a stag and wild boar beautifully chiselled), Oriental vases with Gouthière mounts, a wonderful *commode, tempo Directoire* with *plaques* of Wedgwood framed in the finest metalwork, and various other examples of the periods of Louis XIV, XV, XVI, may be studied in place. A bedstead made by Bennmann from the designs of Philippe de la Salle is a gem of its kind. The whole arrangement is that of the Wallace Collection, each room being arranged as a dwelling-room, with the exception that cords or rails protect the objects from ignorant hands. The walls are decorated with pictures — among others, some pastel portraits by de la Tour.

The collections which used to be in these rooms seem to have been dispersed among the various *musées;* but the drawings have been placed elsewhere, though they are not yet visible to the public.

There is one arrangement at the Louvre of which one may speak with disapprobation. Formerly we were allowed to keep our sticks and umbrellas. During the Exhibition we were compelled to leave them with the custodians, and, like the prices at the restaurants, the disappearance of the Exhibition has not brought one or the other to its normal condition. If the Louvre had but one entrance, like the National Gallery or British Museum, it would not matter; but to be obliged to tramp all round the building to fetch one's umbrella when one has already been round it is hard, and adds much to the fatigue. I cannot see why the *gardiens* could not send the sticks, etc., round to the main entrance where the public might find them. The leaving of our property is not our desire — it is for the good of the museum; therefore I think it very hard to have to leave my umbrella in the Place du Carrousel, and then to be obliged to return there to fetch it, although the end of my promenade may be at the Church of S. Germain l'Auxerrois. It is fatiguing enough to make the tour once; it is most irritating to be obliged to tramp back again the whole distance. S. Beale.

MUNICIPAL SOCIALISM.

THE State Department has published in advance-sheets of the Consular Reports a long report by James Boyle, United States Consul at Liverpool, on "Municipal Socialism in Great Britain." The Consul notes a quiet but gradually increasing development in Great Britain of that phase of socialism known as "municipal trading," or the ownership and operation of public utilities. In 1875, he says, the capital invested in municipal undertakings in Great Britain was $465,000,000, and in 1900 it was $1,500,000,000. He adds:

"There are now in Great Britain 931 municipalities owning waterworks, 99 owning the street-railroads, 240 owning the gasworks, and 181 supplying electricity. Most of these are in England. Municipalities were not allowed to work the tramways until 1896. It is estimated that half of the gas-users in England use municipal gas. In a number of places — Liverpool among them — the municipalities supply electricity for lighting and power, while the gas-supply is still in the hands of private corporations. In the case of Liverpool, the gas-company is quite willing to sell to the municipality, but the latter will not buy: first, because under the charter of the gas-company the municipality would be compelled to pay a perpetual dividend of 10 per cent to the stockholders, and, secondly, because it is believed that in the near future electricity will practically supersede gas as an illuminant.

"The municipalities of Leamington and Harrogate own Turkish-baths, two of the best at present existing in Great Britain, and Harrogate also gives fireworks-displays at municipal cost. Glasgow, like Liverpool, owns its waterworks and trams, and provides municipal lectures. Glasgow has recently reduced the fares on the tramcars, so that there are now not only halfpenny (1 cent) fares, but a distance of two and one-half miles can be travelled for 2 cents. Universal penny (2 cents) fares will probably shortly be introduced in Liverpool. The "transfer" system, as prevailing in America, is not used in Liverpool, nor in any other British municipality, so far as I know. Glasgow was the first city to establish a "municipal palace." Manchester owns shares in its ship-canal. Out of its municipal-tramway profits, Sheffield has appropriated $75,000 for the erection of shops and business-premises which it will rent. Quite recently the northern townships outside of London bought the well-known Alexandra Palace, where the municipal authorities maintain an auditorium and give

organ-recitals and theatrical, military-band, and variety entertainments of all sorts, and industrial exhibitions. Torquay owns a rabbit-warren; Colchester possesses an oyster-fishery; St. Helen's (a chemical centre in this consular district) supplies sterilized milk; Hull owns a crematorium: Doncaster and Chester own racecourses (the former actually managing the races); Bournemouth owns one of the finest golf-courses in Great Britain; West Ham, a borough of London, owns a stone-flag factory; and Bradford owns a hotel — as does also Liverpool (on its waterworks property in Wales). Bristol has municipalized its docks and harbor, at a cost of between $10,000,000 and $15,000,000.

"The docks of Liverpool are municipalized in a modified way. The system is peculiar to Liverpool. This vast estate, valued at several hundreds of millions of dollars, is administered by a public trust, nearly all the members of which are elected by those who pay dock-dues, and the profits, after deducting expenses and payment of interest on capital account, go to improvement, and not to the benefit of a private corporation. The probability is that the London docks will before many years be managed under either the Bristol or the Liverpool plan. Nottingham, in addition to owning parks, markets, artisan dwellings, baths and a hospital, has bought a castle and a forest, and has a natural-history museum and a school-of-art, and was the first municipality in Great Britain to have a university college. The last item gives occasion for the statement that several English cities have within the last year or so taken up the question of local universities. Birmingham has established one, and Liverpool will shortly follow suit.

"Liverpool is one of the foremost cities in municipal socialism. It owns the waterworks (one of the best systems in the world); it operates the street-cars; it supplies the electric light and power; it has one of the largest and best public-bath systems anywhere, and proposes to erect the finest Turkish-bath in Europe; it provides public laundries for the poor districts; it furnishes flowers and plants for the windows in the slums; it sells sterilized humanized milk for the children of the poor at cost price; it has a salaried organist to play its famous municipal organ; it gives municipal lectures — and all these in addition to the usual undertakings of municipalities, such as parks with concerts, technical schools, etc. But the greatest socialistic undertaking by the Liverpool municipality is that of providing dwellings for the very poor, the dispossessed tenants of demolished unsanitary dwellings of the slums.

"The one great predominating question in connection with municipal socialism is the 'housing question' — that is, the demolition of 'slums' and unsanitary dwellings and the erection by the municipality of suitable dwellings in place thereof. Americans who have never been here can have but little conception of the terrible conditions existing in many of the large cities of Great Britain as to the housing of the very poor. This condition is a heritage of former social and economic conditions, as well as of feudal land-laws, and of the past indifference both of the municipalities and of Parliament, as well as of the public generally — even, it may be said, of philanthropists. But heroic efforts are now being made in many of the large cities, and Liverpool is in the front rank in the efforts to remedy this deplorable state of affairs. Many difficulties have been confronted and overcome which at first were thought to be insurmountable — and these in addition to the perplexing moral and social questions involved. . . .

"The Liverpool municipal dwellings are mostly in the form of blocks of tenement-houses, or 'flats,' three or four stories high. The Local Government Board (a bureau directly under the control of Parliament) insists upon certain provisions to meet the necessity of dispossessed tenants before sanctioning demolition operations. Until 1899, there had been a conspicuous failure to meet this obligation, but since then the wants of dispossessed persons have been carefully foreseen and met. The present policy is to have blocks of dwellings ready within convenient distance, into which dispossessed tenants can go immediately they remove from the condemned property. Most of these tenants are dock-laborers or a like class. It is claimed that Liverpool alone among the municipalities of England and Scotland has been successful in supplying a type of building within the financial means of the poorest of the poor. A single room can be had for as low as 45 cents a week. The rent of two rooms ranges from 60 to 80 cents; that of three rooms, from $1 to $1.10; that of four rooms (the largest suites provided), from $1.25 to $1.50. The fixtures are simple, but superior to those supplied in like dwellings by private landlords. In a few dwellings, hot water is supplied. Others have gas, paid for on the 'slot' principle. Two cents' worth is sufficient for four or five hours' consumption by one burner. Since Liverpool went into this enterprise, it has paid $1,925,000 for demolished property, and, in addition, several pieces of land have been purchased, costing $335,825, for the erection of municipal dwellings. The cost up to date for construction alone has been $732,875. The total burden on the local taxation as the result of these combined operations amounts to 1¾*d.* in the pound sterling, or 3½ cents on every $4.86. The rents paid are insufficient by about 2 per cent to meet the cost of the dwellings, without counting anything for a sinking-fund, depreciation, etc. The present effort of Liverpool is to provide housing for the dispossessed tenants of condemned slums. It will probably take 12 years to complete this task. Then, the question of providing better accommodations for artisans and mechanics will possibly be faced. Liverpool, it is said, owns more revenue-producing real-estate than any other municipality in the world, its income from this source being about half a million dollars a year.

"The London County Council has within a recent period taken hold of this 'housing question' with a firm and comprehensive grip. There will not be as much compensation paid to owners of slum property as formerly. One scheme adopted by the London County Council provides cottages for 8,000 people; another (and this is on an estate outside of the London boundary-line) will accommodate 6,000 people; and a site has been bought where 42,000 are to be accommodated in pretty little cottages, with gardens. London undertakes to provide for the artisan class as well as for the 'casual,' and in that particular it is in advance of Liverpool. . . .

"The claim is made that the best-governed towns in Great Britain and the towns that have the least taxes are those where municipal socialism prevails. But this claim is strongly controverted, especially as to ultimate results; and the opponents of municipal socialism charge against that system a tendency to extravagance, jobbery, official indifference and lethargy, and the broader charge is made that the system contracts and paralyzes individual effort and enterprise. Yet it should be kept in mind, in connection with this criticism, that municipal socialism has in some cases been embarked upon almost out of necessity — as, for instance, in the case of the housing of the poor in Liverpool, where private enterprise has not only failed absolutely to solve the problem, but has not even alleviated its most crying evils."

THE REGISTRATION OF ARCHITECTS IN NEW JERSEY.

JERSEY CITY, N. J., May 22, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT:—

Dear Sirs: — I have been requested by the New Jersey State Board of Architects to send you a copy of the enclosed notice which has been published, requesting all architects to register under the law recently passed. Yours truly,

HUGH ROBERTS,
Secretary and Treasurer, State Board of Architects.

STATE OF NEW JERSEY. — STATE BOARD OF ARCHITECTS,
1 Exchange Place, Jersey City, N. J.

Charles P. Baldwin, *President;* Hugh Roberts, *Secretary and Treasurer;*
Arnold H. Moses, Charles Edwards, David B. Provoost.

JERSEY CITY, N. J., May 19, 1902.

NOTICE is hereby given to all architects practising the profession of architecture in the State of New Jersey as defined in "An Act to Regulate the Practice of Architecture" (approved March 24, 1902), and in effect July 1, 1902, that they should now apply for a certificate to practise architecture under Sections 9 and 10 of said law.

For the information of those who desire to secure certificates the Act has been printed in full by the State Board of Architects, and copies will be furnished on application, together with a form with affidavit attached that has been approved by the Board.

The privilege extended to practising architects by Sections 9 and 10 of said law will expire July 1, 1902, after which another form of application for examination under the provisions of the Act will be furnished when requested.

All certificates issued on the present form of application and affidavit will be forwarded to the applicant after the payment of the registration fee of $5.00, said amount being payable after notice of acceptance of application is received by the applicant from the Secretary. All certificates issued are subject to the powers of revocation vested in the Board by the above-mentioned Act. HUGH ROBERTS, *Secretary.*

NOTES AND CLIPPINGS

Repairing a Range-boiler. — A correspondent of the *Metal Worker* gives the following account of a method of repairing a range-boiler resorted to by a man who did not wish to incur the outlay for a new boiler when the old one had begun to leak. The boiler was made of galvanized-iron and the shell was too thin to permit of the use of a drift-punch to make an opening to be tapped so as to be stopped by means of a screw-plug. In the first place, as the owner was somewhat handy, he emptied the boiler and soldered up the hole, but this did not last more than a few days after the boiler became hot, and it began to leak again. He then employed a plumber to fix up the boiler so that it would stand until he could afford to have the old boiler replaced by a new one. The plumber removed the old solder and cleaned off the boiler, making a perfectly round hole, where it leaked, large enough to take a ¼-inch bolt with a soft-copper washer on the inside. The bolt and the washer were secured together and dropped into the boiler through the hot-water opening at the top, a piece of thread being tied to each end of the bolt. It was a simple matter to insert a wire through the hole and catch the thread upon the lower end of the bolt. The bolt was then drawn through the hole and another soft-copper washer placed on the outside. A cement composed of litharge and glycerine was worked into the hole between the inside of the boiler-shell and the washer. Some of the same cement was put on the outside of the boiler-shell under the washer. When enough cement was put on the washers were drawn up tight against the shell by the tightening of the nut. When the cement had hardened it not only made a perfectly tight job, but also one that has stood for a considerable time. This method has been found serviceable for stopping holes in iron tanks, pipes and other places, where replacing the material would have caused considerable expense. It has proved its efficiency where the material is not thick enough to be drilled and tapped to be filled with a plug. The same method can be adopted for stopping sand-holes in thin castings.

This is the man for whom it was planned,
And this is the scamp who put it in hand,
And filled-in the footings with stones and sand,
With no cement, and said, "It's grand!"
When building the house that Jerry built.

These are the bricks, as soft as cheese,
That broke in two if you chanced to sneeze;
Said Jerry: "The man what don't like these,
Lor', blow me! he *will* be 'ard to please;
They'll last for months — unless there's a breeze,"
In the beautiful house that Jerry built.

These are the windows of packing-case wood.
Said Jerry: "Of course it's understood
It'll be extra for windows of real wood;
These 'ere are special, and much too good"
To go in the house that Jerry built.

This is the rubbish that blocked up the drain.
Said Jerry: "Now don't you labor in vain;
Fill it in — it'll never be seen again,
It's ten to one he won't complain;
The cellar is meant to collect the rain"
That falls on the house that Jerry built.

This is the elegant panelled door,
With the natural finish left by the saw,
Which warped till its panels fell out on the floor.
He bought it for six shillings — but, "Lor'!"
Said Jerry, "it looks worth ten bob more" —
Too good for the house that Jerry built.

These are the slates — some small, some great,
Most were crooked, but a few were straight,
Each kept in place by the next one's weight;
Said Jerry, instructively, to his mate:
"I saves my nails and I trusts to Fate,"
When building the house that Jerry built.

These are the locks he bought for a song,
They work three times and then go wrong.
He said: "It's lucky they ain't too strong;
There'll be some repairs a-coming along"
To be done to the house that Jerry built.

This is the price the purchaser paid
(He'd made some cash in the grocery trade);
"Dirt cheap," said the man of trowel and spade,
As the cheque in his horny hand was laid;
"And a better house has never been made"
For the price of the house that Jerry built.

This is the band that came up the road;
The drummer drummed and the cornet blowed,
And as it passed, the house like a flash
Fell suddenly down with a fearful crash,
And all that remained was a heap of smash;
And the owner said words like "blow" and "dash,"
And he stared in amaze at the heap of dust,
While the more he stared the more he cussed
At the vanished house that Jerry built.

A. E. F. in "Property."

The Island of Philæ and the Assuan Dam. — As usual, a number of interesting facts are to be gleaned from Lord Cromer's annual report of Egyptian affairs. He devotes a considerable amount of space to a description of the precautions which have been taken to preserve the foundations of the ruined temples on the island of Philæ, which will be submerged annually when the reservoir at Assuan is completed. He says that the Egyptian Government has been attacked by the engineers for paying too much attention to the artists and archæologists, and by the latter for paying too much attention to the engineers. His own opinion is that to have deprived the people of Egypt on artistic and archæological grounds of the enormous benefits which they will derive from the construction of the Assuan dam would have been perfectly unjustifiable. On the other hand, he declares that everything possible has been done to meet the wishes of those who represent the archæological and artistic aspects of the question. — *N. Y. Evening Post.*

The Invalidity of unsealed Corporate Contracts. — We have repeatedly pointed out the risks which architects, engineers and contractors accept when they make arrangements with corporations and other local bodies without taking the precaution to have the agreements stamped with the common seal in each case. There is so much confidence in a public authority that individual security is neglected. Recently another instance of what we may call the fatality came before the Courts. Mr. Lawford, a civil-engineer, who is known in connection with drainage work, sought to recover £169 14*s.*, remuneration for preparing a report and plans for a scheme of sewerage which the Billericay Rural District Council were about to undertake. The Local Government Board held an inquiry and approved of the plans and estimates. Tenders were sent in, but one was not accepted. It was not denied by the defendants that Mr. Lawford's work was duly performed, or, in other words, there was no defence except the fact that as the common seal was not affixed to the agreement, it was therefore of no value. It is always a disagreeable duty for a judge to be compelled to give a decision when he knows that by it gross injustice must be done to a plaintiff. But so long as the judgment which was given by Lord Denman in Church *vs.* Imperial Gas Company is unreversed there is only one course open, and that is to say that an agreement is illegal which is without a common seal. Lord Denman's words should be remembered as a warning by all who have business with corporations of all kinds, for he said: "The general rule of law is that a corporation contracts under its common seal; as a general rule it is only in that way that a corporation can express its will or do any act. That general rule, however, has from the earliest traceable periods been subject to exceptions, the decisions as to which furnish the principle on which they have been established, and are instances illustrating its application, but are not to be taken as so prescribing in terms the exact limit that a merely circumstantial difference is to exclude from the exception. This principle appears to be convenience amounting almost to necessity. Wherever to hold the rule applicable would occasion very great inconvenience, or tend to defeat the very object for which the corporation was created, the exception has prevailed; hence the retainer by parole of an inferior servant, the doing of acts very frequently recurring or too insignificant to be worth the trouble of affixing the common seal, are established exceptions; on the same principle stands the power of accepting bills of exchange and issuing promissory notes by companies incorporated for the purposes of trade, with the rights and liabilities consequent thereon." In Hunt *vs.* Wimbledon Local Board the architect's plans were utilized, but although the Board had benefited by them the claim for payment was rejected on the ground of informality. How such a defence can be set up by an English authority is beyond comprehension, but the fact remains that payment can be successfully evaded by the absence of a seal. — *The Architect.*

The widest Streets. — In the *Clay Worker* Mr. W. C. Dodge says that Washington, D. C., has sixteen streets, or avenues, each 160 feet wide, and many others 120 and 130 feet in width. Fifty-four per cent of the entire area of the National Capital is occupied by its streets, avenues and alleys, a larger proportion than that of any other city in the world. The street-area of a few of the principal cities is given as follows: —

Washington, D. C.	54 per cent.
Vienna	35 per cent.
New York City	35 per cent.
Philadelphia, Pa.	29 per cent.
Boston, Mass.	26 per cent.
Berlin	26 per cent.
Paris	25 per cent.

Puvis de Chavannes as a Caricaturist. — The lighter side of a great artist's genius is frequently disclosed only after his death. This was the case with the mural painter Puvis de Chavannes, who is remembered for the grave beauty of his decorations in various French cities and in Boston; it is only recently that his minor studies and caricatures have been exhibited in Paris. Apropos of this exhibition *Figaro* recalls an interesting anecdote. The art-critic Count Delaborde, shortly after his election to the Academy of Fine-Arts, took occasion to say of Puvis that "his talent represented the negation of all the essential principles of art." This comment Puvis remembered until Delaborde, now become Perpetual Secretary of the Academy, in a public address perpetrated the ineptitude of declaring that in the entire production of all the centuries he recognized only one work which really deserved the title of masterpiece — namely, the Parthenon. This dictum was the occasion of a caricature by Puvis, entitled "The Ruins of M. Delaborde, drawn from the life by M. Parthenon." Amid the ruins of the dome of the Institute sat the eminent Perpetual Secretary, as a mutilated statue. The face, however, was intact, the head highly polished, and — most notable trait of all — the eyes tightly closed. Below, one read the name of the artist: "To M. Delaborde, gratefully and respectfully, M. Parthenon." — *N. Y. Evening Post.*

NOTES AND CLIPPINGS. 80

IT would take a very strong and nearly unanimous appeal from our subscribers to induce us to continue the form of publication which, during the current quarter, has been given experimentally to our International Edition. We are not satisfied with the practical working of the new method, which seemed to have the promise of many desirable possibilities in its favor, and believe that no mistake will be made in returning at the earliest practicable moment to the original form of publication. From the first issue for July, therefore, subscribers to the International Edition will again receive their copy in its familiar blue-covered weekly form.

ARCHITECTS, to many of whom Mr. Edward Robinson is personally known, will be pleased to hear of his unanimous election as Director of the Boston Museum of Fine-Arts, in place of General Charles G. Loring, who, after holding that position since the organization of the Museum, recently resigned it. Mr. Robinson has long been reputed one of the best American authorities on classical antiquities, which he has studied for many years. After his graduation from Harvard University he spent five years in Europe, much of the time in Greece, and, on his return, was appointed Curator of Classical Antiquities in the Boston Art Museum. This office he has held ever since, but he has, in the meantime, been employed to assist in the formation of collections of casts and other objects for various institutions, making several trips to Europe for the purpose, and has published several essays of great interest on his favorite topics. Personally, Mr. Robinson is peculiarly fitted for a position which demands, not only industry and learning, but great patience and tact in dealing with the perplexing problems incident to the management of a great semi-public institution, and his friends, and the community in general, will join in the hope that he may be spared to occupy it for many years.

THE Baltimore Art Commission has distinguished itself by arresting in the bud the operations of the Superintendent of Public Buildings, who had men at work "chiselling off" the dirt on the faces of the figures on the Battle Monument. The Monument was certainly dirty, and the Superintendent, who seems to be a friend of neatness, if not a very discriminating one, gave authority to a person to "clean" it. The latter is said to have begun his work by applying a strong acid to the marble, and, as this does not seem to have worked rapidly enough, he followed it up with a chisel. Fortunately, some one saw what was being done, and reported it to the Art Commission, which immediately applied to the Mayor to have the work stopped; and the Mayor readily complied with the request, at the same time appointing a committee of the Commission to investigate the matter, and make recommendations. The Committee, which included two architects, discovered that some of the reliefs on the Monument had been nearly destroyed by successive cleanings of the same kind. As the members picked up fragments of marble around the Monument, which had been knocked off by the zeal of the cleaners, it may be imagined that their prediction, that a few more years of such treatment would ruin the artistic beauty of the structure, was fully justified, and their recommendation, that, for the future, the cleansing of marble sculpture belonging to the city should be limited to the application of water with sponges or bristle brushes, will, we hope, be kept in mind, not only in Baltimore, but elsewhere.

AS it is unquestionable that the Baltimore Monument, after eighty years of existence, had become very black, and as marble sculpture streaked with black and brown is not so attractive as new work, it is worth while to consider whether, under the conditions which necessarily prevail in large modern cities, the placing of marble statues out of doors is not a mistake. In Washington, perhaps alone among the principal American cities, marble sculpture has been able to resist nearly a hundred years of weathering without great injury, but, elsewhere, bronze seems to be the only successful material for municipal decoration. In Paris, the local limestone takes, with age, a brown color which is not unpleasant, and it is possible that some of our limestones or marbles might weather in a similar way; but those which have hitherto been used seem to resemble the London stone in assuming a dingy, disreputable color. Fortunately, none of the stones used here for sculpture are subject to the mangy cutaneous disease characteristic of the London work; but there is room for a great deal of discrimination in the choice of material. Undoubtedly, our granites might be used with advantage, so far as durability is concerned; and some of the milky white granites, as well as the black and red Maine granites, would lend themselves to artistic effects.

TWO accidents to grain-elevators have taken place within a few days, each of which teaches an interesting and important lesson. In one case, the Peavey Grain Company, of Duluth, with an intelligent enterprise which cannot be too highly commended, had sent men to the Danube Provinces, to study the small grain-elevators in use there, made of concrete. On their return, plans were made for an elevator of the same sort, but on a much larger scale. We are told that the plans were "carefully studied," but, judging from the newspaper accounts, it seems impossible that any competent architect or engineer could have been concerned in preparing them, or with the supervision of their execution. In general, the structure consisted of a number of cylindrical bins, each one hundred and four feet high, standing three feet apart. We are not told the diameter of the bins, but only that they were of concrete, strengthened by "steel tie-rods one and one-half inch wide," spaced eight inches apart the whole height of the bin. The thickness of the tie-rods is not given, but they seem to have been mere bands, and the intelligence with which the dimensions and the spacing were made the same at the top of the bin, where the lateral pressure was nothing, as at the bottom, where it amounted to many tons, seems to have directed also the mixing and laying of the concrete work, which was carried up at the rate of thirty inches a day, the whole being completed in eighty-six days. In order to utilize all the space, short walls of concrete were made, connecting the nearest points of the circular bins, thus forming bins with concave sides. A few days ago, the building was tested, by filling one of these concave-sided bins with wheat. Dry grain of this sort exerts a lateral pressure very similar to that of a column of water, so that the lateral pressure at the bottom of a bin one hundred and four feet high would not be far from fifty pounds to the square inch. Supposing the circular bins to have been ten feet in diameter, and one of them to have been filled, the lateral pressure on a section at the bottom, eight inches in height, would be about seventy-two tons. As concrete, particularly concrete made so rapidly as this seems to have been, has very little tensile strength, the designer of the structure seems to have depended, for resisting this enormous strain, on a little steel hoop, an inch and a half wide. Calculated with reasonable prudence, the lowest hoop should have been about four inches wide, and an inch thick, the strength required diminishing from this point to the top; and the joinings would have demanded double fish-plates, and many large rivets. Even then, the tie-rings could not resist a pressure from the outside, which would bend them inward, without calling their

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

tensile strength into play; yet it was just this strain to which the very inadequate hoops actually used were first subjected, by filling, at the test, one of the concave-sided bins with grain, without providing a counteracting pressure by previously filling the cylindrical bins around it. It is not surprising to read that the bin had hardly been filled to the top when it burst, carrying away with it the empty bins around it, and opening in the side of the building, according to the newspapers, a hole sixty-five feet high and fifty feet wide. The owners, with true American courage and persistency, have, as we are told, determined to make repairs, and try another test, believing that the principle of construction is a good one, and that errors of detail were the source of the trouble. In both these points we heartily agree with them. With proper ties, the cylindrical concrete bins should be very durable, and perfectly fireproof, and the concave-sided spaces between can be safely used for storage of grain, if the surrounding circular bins are full, but not otherwise. Of course, it is easy to provide for having the concave-sided bins always filled last, and emptied first; and, with greater knowledge, the system is likely to come into extended and successful use.

THE other grain-elevator mishap affords a good illustration of the ignorance which prevails in the community in regard to the requirements of a fireproof building. A grain-elevator was built, not long ago, by the Canadian Pacific Railroad, which was intended, we are told, to be "absolutely fireproof." The main building was of steel, "heavily constructed," steel being known to be a heavy material, and the floors were of steel plates. There was no wood in the building, "except four cleaning-machines and two elevator-legs," but it was so full of dust and chaff that, when fire started in it, the steel is said to have been actually melted by the intensity of the heat. With such material to feed a fire, a better construction to secure speedy ruin could hardly have been devised. The steel seems to have been exposed everywhere, and the steel-plate floors, of course, curled up as soon as they felt the heat, allowing the flames to run up freely through the building, which formed simply an enormous blast-furnace, as long as the fuel lasted. Spruce boards would have been better than steel plates for floors in such a building. At least, they would keep the fire back until they were burnt through, while metal begins to curl long before it reaches a red heat. *Fire and Water* says, mournfully, that the total destruction of this building has "taken everybody by surprise." It certainly has not taken any architect by surprise, and the people who, like *Fire and Water*, are in search of the "absolutely fireproof building" can easily obtain, by applying to any architect, information which will, at least, prevent them in future from attributing fireproof qualities to any structure of exposed steel used for operations which produce inflammable dust and residues.

MR. JAMES BROWN LORD, one of the most brilliant of the New York architects, died a few days ago after a long illness. Mr. Lord was of distinguished family, his grandfather having been a famous lawyer, while his mother was a daughter of James Brown, the founder of the banking-house of Brown Brothers. He graduated at Princeton University in 1879, and immediately began the study of architecture, under William A. Potter. On beginning practice on his own account he found ready employment, and designed many public and private buildings, including the two Delmonico buildings; the White Plains Insane Asylum; the Babies' Hospital, and the new and magnificent Appellate Court-house, in Madison Square. This beautiful building, of which we have published many illustrations, deserves to rank among the notable works of American architecture yet produced, and we trust that its brilliant and lamented author may be worthily commemorated in it.

JEAN JOSEPH BENJAMIN CONSTANT, one of the most famous of modern painters, died in Paris a few days ago, at the age of fifty-seven. Benjamin-Constant, as he was always called, received his early education in the South of France, and entered the Paris School of Fine-Arts with a high reputation from the preparatory school at Toulouse. He went through the usual routine in Paris, under Cabanel, and was twice "logiste" for the Prize of Rome, but, before his third trial, he came across the works of Fortuny, and, seized with the desire of becoming a colorist of the Fortuny sort, he left Paris, and, soon after, went to Turkey, as an attaché of the French Embassy at Constantinople. Here and in Egypt he studied Oriental color to his heart's content, and his most popular pictures have been of Oriental subjects. Of late years, he had been almost continually engaged in painting portraits, many of them of Americans, and he made several visits to this country in fulfilment of engagements for this purpose. Although not the most sympathetic of French painters, his work was always solid and inspiring, with a certain nobility of character which found quick appreciation among Americans, who, whatever may be said of their ignorance of the details of art, are very sensitive to its higher qualities.

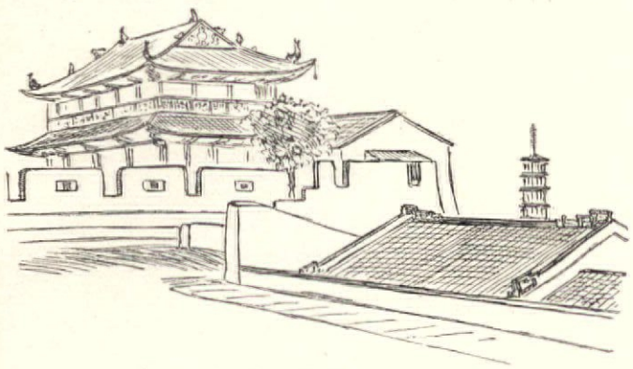
THE Art Students' League of New York offers four prizes for the best work done in the schools of the League during the winter term, and the award for the term now concluded has just been made. The prize in sculpture, of one hundred dollars, given by a member of the League, was awarded to Miss Abastenia Eberle, a second recompense, consisting of a year's free tuition in the classes of the League, being gained by Mr. John Burdick; while two honorable mentions were given. In design, a prize of fifty dollars, offered by Mr. William T. Evans, was awarded to Mr. Wallace Fahnestock; and a similar prize, for the best architectural composition, was carried off by Mr. George F. Of, Jr. The Summer School of the League begins June 1, continuing through June, July, August and September, with daily classes in drawing and painting from the life or the antique, four hours daily; still-life work in any medium; and instruction in practical book-illustration. Every Saturday morning a sketch class, with costume models, is open free to students of other classes, and to special students for a fee of three dollars for the first month, and two dollars a month thereafter. For the regular daily courses the fee is seven dollars for a single month, or five dollars per month for two, three or four months. It is hardly necessary to say that the instruction given in all the League classes is of the highest order, and students find there the invaluable encouragement and stimulus of a great school of art which now has nearly a thousand members.

THE question of building a dam across Charles River, at Boston, so as to form a basin, always full of water, extending from the city water-front to Watertown and Newton, in place of the present tidal stream, pleasant to look at when the tide is high, but filthy and disgusting at low water, is still under discussion, and some interesting points have been brought out. The main objection to the construction of the dam has always been that the checking of the tidal flow might injure the harbor below by interfering with the scouring action of the current in the channel; but this objection has been answered by a communication from Professor Davis, of Harvard University, who, speaking as a geologist, points out that the channel of Boston Harbor was never due, as the engineers of forty years ago imagined, to the erosion of the waters of Charles River, but was formed, probably by glacial action, when the present harbor bottom was above the level of the sea; and that the subsidence of the land, which followed in many places the recession of the ice, carried the surface down without change, the valleys among the glacial moraines forming the channels of the harbor of to-day. Although the Charles River undoubtedly availed itself of the outlet afforded by the new channels, it did not form them, but, on the contrary, brought down, as it still continues to do, mud and silt to fill them up; and the tidal currents, which in some cases, as Professor Davis says, run swiftly enough through the old channels to keep sediment from accumulating in them, bring to other places enormous quantities of sand. The beaches of Nantasket, Cohasset and Revere were formed in this way, out of sand brought by the tides, probably from islands in the outer harbor, which have now been entirely washed away, and the material of which they were composed deposited at favorable points. The salt marshes of Dorchester and Quincy have had a similar origin, and it would appear that the scouring action of the tides, while it exists in certain places, is, so far as Boston harbor is concerned, very limited, and is liable to variations dependent upon the gradual changes in the configuration of the shore brought about by tidal action of another kind. Whether the damming of the river at its narrowest point, as is proposed, would affect the scouring action, Professor Davis does not, as yet, undertake to say, the evidence available for studying the changes which have taken place in the channel being very meagre; but it is probable that new examinations will be made, and a clear light thrown on this very interesting and important problem.

JOURNAL SKETCHES IN CHINA.[1]—V.

CANTON.

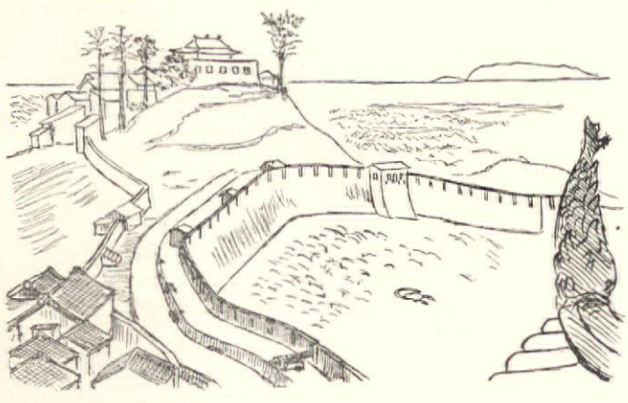
AFTER spending a few interesting hours at this place, Mr. Sampson accompanied me on a trip to one of the city-gates and around the city-walls. In the palanquin, or chair, one sits rather high, as the poles supporting it are attached to the chair nearly two-thirds



View from City Wall, Canton.

from the top, so that one gets a better view than in riding in the Japanese *kago*, which is entirely below the suspending pole, and one is near the ground. The encircling wall of Canton is 20 to 25 feet in height and of great thickness. It is nearly seven miles in length and consists of an immense mass of masonry resting on a sandstone foundation. The top of the wall is reached by steps and also by gently rising inclines. At intervals are gates over which are large building structures. The gates within have a semicircular wall perforated by another gateway. In the days of bows and spears, which the Chinese still retain, these grim walls must have rendered a city almost impregnable, but they offer little resistance to foreign artillery and dynamite. A broad roadway is found on top of the wall which is apparently never used except by loiterers like ourselves, and yet this thoroughfare is wider and cleaner than any avenue I found in the city with its crowded thousands. Such are some of the exasperating perplexities that one encounters in China. In the following sketch of the walls a huge building is shown through which the road passes and below which is one of the city gateways. The building was erected in the fifth century and is leaning slightly. The crest of the wall is pierced for cannon, and, at intervals, were small iron cannon, rusted and utterly neglected. The obsolete and puerile methods of defence explained at once the easy capture of the city by the English and French in the Opium War.

I rode in my chair for a considerable distance and then got out and walked. In the crevices of the wall and in a shady nook the last violets of the season were blooming. Our walk led us to a five-storied pagoda built in the thirteenth century. From the top of this structure a fine view of the city was obtained. It was interesting to look over this vast city where no tall buildings or factory chimney overtopped the uniform low level of the roofs. Here and there were the imposing roofs of Buddhist temples and the many-roofed pagodas rising conspicuously. It is a remarkable sight to have a clear view across a city to the country beyond. The absence of coal-smoke accounted for the clarity of the atmosphere. This condition was markedly so in Tokio twenty years ago and presented an agreeable and startling difference from the smoke-begrimed cities of Europe and America. From the pagoda I made a sketch of the wall which we had just traversed. In the distance is seen a cluster of Buddhist buildings, monasteries and the like. Outside the walls, on

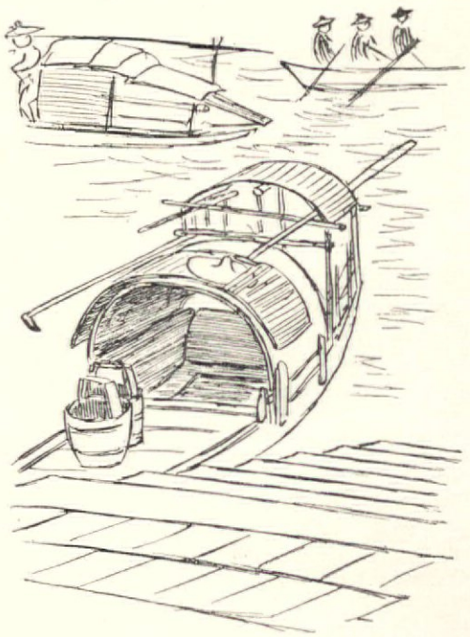


View from five-storied Pagoda, Canton.

a sloping hillside, were thousands of little hummocks of earth, each having a tablet of some sort; here and there an amphitheatre-like structure of stone marked the burial-place of some wealthy mandarin. I examined the region afterwards from the wall and could not find a trace of tree, flower, green leaf or path even. The shocking state of the place, in view of the fact that the Chinese are supposed to worship their ancestors, was in marked contrast to the care and devotion shown by the Japanese, or by our own people, in their burial-places. The ground around the pagoda was covered with a tangled mass of dead leaves and shrubs. Here I found the shells of a large snail, a species which as a boy I had preserved in my cabinet as a rare and valuable object. The ground was strewn with them and a little boy who had observed me collecting them at once gathered a handful and brought them to me, at the same time promptly holding out his hand for pay. A few people were in the enclosure gathering the dead grass and twigs for fuel.

Tired out with the novel and interesting experiences of the day, I reluctantly gave orders to return to the hotel, and again we passed through the same seething mass of people crowding the narrow streets. The night was spent in writing up my notes. My room opened on a platform directly over the banks of the river, and the rear of the hotel came into immediate contact with the Chinese houses. The river was almost as active with traffic as the streets. A continual humming sound with occasional shouts came over the water, and from the region behind the hotel the same eternal din of the various activities was going on, though it was past midnight; this din was now and then punctuated by loud explosions of cannon-crackers, or small cannon, in saluting some high official just returning or departing from his house. With this and the banging of drums and every conceivable form of racket sleep was wellnigh impossible. The streets of an old New England town on the night preceding the Fourth of July are the nearest approach to it, and are a manifestation of the same heedless barbarism.

The manufacturing activities seem to be as lively at night as in



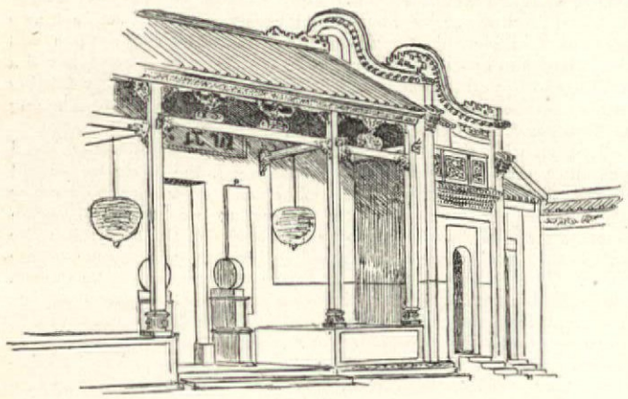
Boats on River, Canton.

the daytime. I walked out back of the hotel at midnight, going through several streets, not daring to go far, however, lest I should be lost. The streets were certainly not so crowded as in the daytime, the shop-doors were closed, but through the crevices glints of light could be seen and the coppersmiths and carpenters and other artisans were apparently just as active as in the daytime, judging from the various sounds that issued from these places. Every one familiar with the appearance of the Chinese laundries in our country will recall the fact that no matter how late one may pass them at night the Chinese are usually found at their occupation. It is said that the Chinese farmer utilizes the moonlight for his work and one can readily believe it.

The next day I visited a Buddhist temple. In general style of architecture, with gateway, huge, carved figures as guards on each side of the entrance, and the various appliances within, the temple followed closely the Japanese type. In the inner court were twenty or more priests chanting at their devotions, with a few curiously-inclined Chinese looking on. Such dreary, dirty-looking priests, shoes, stockings and all, fairly dingy with dirt, presenting a striking contrast to the same class in Japan! The enclosure had evidently never been swept; sticks, dead leaves and noisome pools were everywhere. Back of the temple was a famous flower-garden which was in an equally dilapidated state. There were, however, some interesting evergreens in large flower-pots, which had been artificially trimmed and trained to represent various objects, such as a fan, a kind of fruit, figures, etc. The figure of a man was quite remarkable in its way, though the feet, hands and head were made of some other material. These curious dwarf-trees were in the midst of broken pots, piles of rubbish and festering puddles of water. During my rambles about the grounds I was aware of a new stench commingled with the other vile odors which filled the air, and wondered what

[1] Continued from No. 1378, page 63.

could be its origin. In an enclosure back of the temple were a number of great fat, lazy hogs, and my guide told me they were never killed, but allowed to live and die under the care of the priests of the temple. They were wallowing in their filth, swarming with flies, and spreading over the neighborhood a most horrible stench.



Ceremonial Gateway, Howqua's House, Canton.

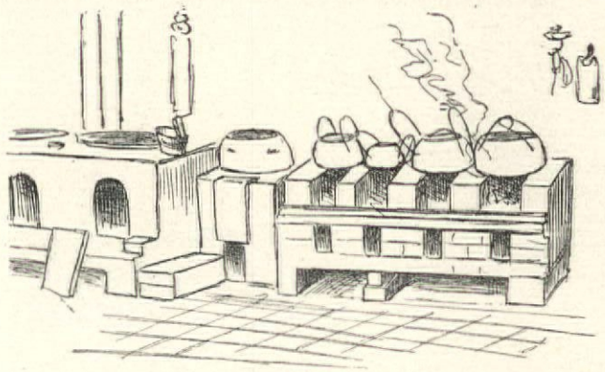
It struck me at the time that here was an emblematical animal that ought to be emblazoned on the Chinese flag beside the imperial dragon. Justice compels me to confess, however, that the hogs were much dirtier than their patrons, though hardly more useless. How many centuries this practice has been kept up I did not learn, but in "*Cleveland's Voyages*" the author records that in 1799 he visited this temple and found several of the priesthood "whose dress bore some resemblance to that of Franciscan friars, and whose business was principally to take care of the sacred hogs. These were about twenty in number and were in an enclosure. They are never killed, but are left to die in the regular course of time; and several of them were so unwieldy that it was not without great difficulty they could move themselves a few feet one way or the other."

With this briefest glimpse of a few temples in two great cities of the Empire I was inclined to believe that Buddhism in China was moribund. I saw no evidence of devotion in the people, no earnest, prayerful attitude as one sees in Japan. The cult apparently excites no religious enthusiasm. What must be expected of a people who, losing their religion, have no science to fall back upon! At night I noticed a Chinese come out of his house, yawning and evidently bored, and burn a little joss-paper before the shrine at his doorway. The burning of paper, incense and lighted tapers seems to be done in the most perfunctory manner. It reminded one of the way in which some people rattle off an unintelligible blessing at home. In all these brief glimpses I could not help contrasting the vigorous and healthy condition of Buddhism in Japan; the fresh-looking temples, though hundreds of years old, so carefully kept and repaired, the surroundings so cleanly swept and in perfect condition, with the utter destitution and decay of the same monuments in China. Here was wrack and ruin everywhere, gnarled roots, by their growth, prying off delicate sculpture from the walls or overturning coping-stones, and no one arresting the destruction.

The few dwellings I had already seen in China were those belonging to the more favored classes, with the exception of the farmhouse near Shanghai. For purposes of comparison it was important to get access to the house of some person of great wealth, and this opportunity was offered me in Canton. By good fortune I got a letter to the family of Howqua — a family of unbounded wealth. The great Howqua was considered one of the richest merchants in Canton. He was known as a person of sterling character and benevolence. In accounts of the Opium War his name often occurs as

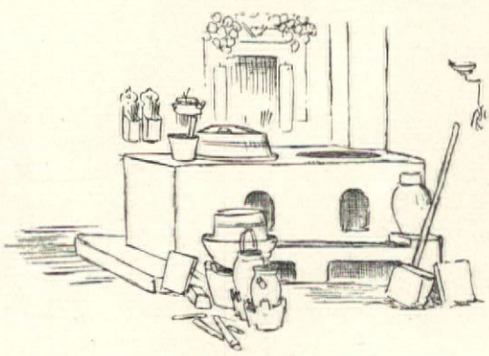
Third Side of Howqua's Kitchen.

mediator. The old Boston and Salem merchants knew him as a man of absolute rectitude, whose word was as good as his bond. He died some years ago, leaving a great fortune to his sons. The house was well known to my guide, who piloted me through the narrow streets to the place. Facing the street was a huge blank wall in which was a single gateway, through which we passed and entered a great square courtyard paved with stone and surrounded on three sides by walls of considerable height, one of which was the wall through which we had passed; the fourth side, which ran at right angles to the street, appeared to be the front of some fine public building, but was in reality a gateway which led to another court and building containing the ancestral tablets upon which were inscribed the names



Kitchen, Howqua's House, Canton.

of Howqua's ancestors. On the anniversaries of the deaths of these various ancestors the head of the family passes through this imposing gateway in the ceremony accompanying the burning of incense and offering prayer. It is only on these occasions that the gateway is used. The accompanying sketch gives only a faint idea of its appearance. The lower portion was composed of fine-grained granite exhibiting the most delicate and beautiful work and finish; the upper portion was of brick; the long, slender columns were monoliths of the same kind of granite; the cross-beams just below the eaves were of wood and at their junction with the stone were elaborately carved; the cornice was richly wrought in intricate designs and was evidently of terra-cotta; the circular drum-shaped discs of the entrance, as well as all the lower portion of the structure, were fine examples of stonework. The whole effect was quite imposing and architecturally very beautiful. The sketch does but slight justice to its stately appearance, though the outlines and proportions are in the main correct. I had made an appointment to meet a grandson of Howqua's, who, with his brother, then occupied the mansion, and so, after making the gateway sketch, I was guided through an alley across a dilapidated garden, then through a gateway to the mansion itself. After waiting some time one of the brothers finally made his appearance and invited me into the house. His brother soon joined us, accompanied by numerous servants and nurses, the latter bearing in their arms diminutive specimens of humanity, the offspring by wives and concubines of these men who had come into the inheritance. The brothers were not particularly gentle in their bearing, and made no effort to relieve me of the pressure of the crowd about me. Every sketch that I made was rudely snatched from my hand by one of the brothers, who disappeared for awhile for the purpose of showing it to the women, who, by etiquette, could not be seen. The contrast in the behavior of these men with that of the Japanese, high and low, was striking. After some time I was invited to sit down and a most delicious cup of tea was brought me. The various rooms through which I was conducted were marvels in the way of elaborate wood-carving and intricate tracery. I found it useless to attempt any sketch of them. The brothers asked me to make the most impossible sketches, which had I attempted would have involved days of the most assiduous labor. When I asked to see the kitchen they were amazed and expressed their rather disgusted astonishment that I should prefer to sketch this region of the house rather than their more elaborate apartments. I was finally conducted to the place and found it quite as dirty and disorderly as any I had seen. Had

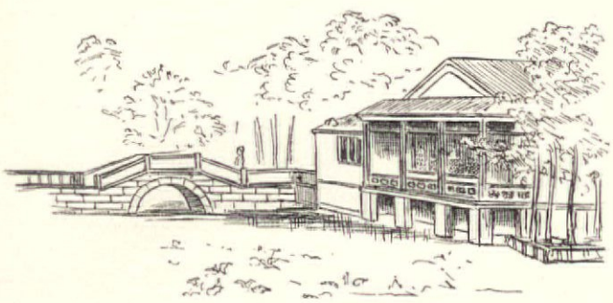


Rice Kettle, Howqua's Kitchen.

the Chinese any realization of what we call dirt, it would be impossible for them to permit a place wherein food for the table was being prepared to be in such a lamentable condition. Filth tracked in from the streets, plus the dirty accumulations that come from their domestic work, made the kitchen a most unsavory place. I cannot but believe that in some of the houses of the richer classes

the apartments must be clean, yet how can we unite such an idea with what has already been seen in the houses thus far described?

Howqua's kitchen was very interesting. I was told that it was a fine example of the old Canton kitchen. It was over one hundred years old and quite different from the kitchens I had already seen, though the differences were probably such as one might see at home

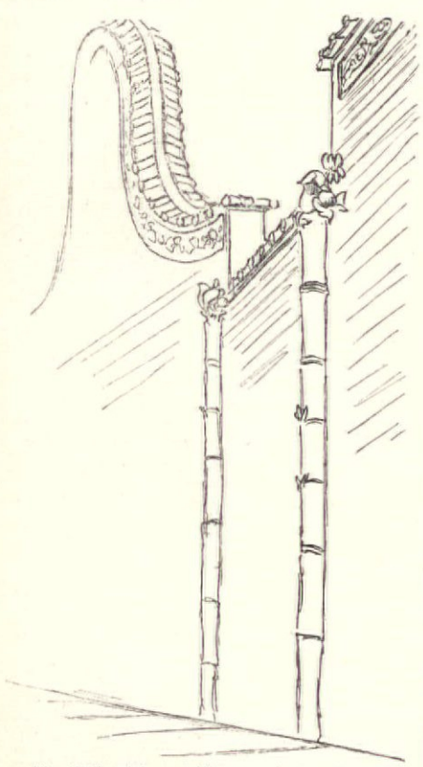


Lotus Pond, Canton.

between the ordinary cast-iron stove and the elaborate range in the kitchen of great houses. Later I saw the interior of a country-house, north of Canton, said to be two hundred years old, and the kitchen was on the same general plan as the one of Howqua's, so I am inclined to believe that the Cantonese affair differs, in many respects, from the northern kitchen, though in both cases, as before remarked, the rice-boilers are very similar. In the drawings three sides of the kitchen are represented. It will be seen that the long range with a number of openings is not unlike the Japanese range, or *kamedo*. The fireplaces are square, and open from top to bottom, and the vessel simply rests on the opening above.

In comparing certain Chinese objects with the Japanese it should be understood that the Japanese have in every case derived these objects from China. The ornamental dwarf-trees, the form of range, the carpenters' tools, musical instruments, etc., of the Japanese have all been derived from China in precisely the same manner that our ancestors, the English, derived similar methods and devices from contiguous regions on the Continent.

The kitchen was a large, spacious room and had all the appliances for preparing a great banquet; copper kettles, large boilers, ladles, etc., were all there and so was the dirt. In this respect it was precisely the same as those I had already seen. Now, the amazing thing about it is this, that if a Chinese cook could be transported to a kitchen of some great house in this country and see the immaculate floor of tile or wood, the polished coppers, the incredible neatness and sweetness of everything, it would not excite the faintest emotion or envy. He would probably look upon it all as a vast waste of human energy, and would say, if he were capable of reflecting on anything, "So long as I keep the dirt out of the food, or at least render it invisible, what's the use of all this effort at dirt removing?" and he might quote our saying which is such a comfort to slovenly people, "Every man has to eat his peck of dirt."



Alley Wall and Cement Water-conductors, Canton.

In the rear of this great house was a large lotus-pond walled-in with brick; on each side were substantial summer-houses in which dwelt the concubines. A glimpse of the large reception-rooms only was permitted. Little bridges such as one sees depicted on old china spanned certain narrow places. Here was every opportunity to make a charming retreat, yet the pond was covered with slime and rubbish, the summer-houses were neglected and dirty, and, knowing the great wealth of the family, one was compelled to recognize this condition of matters in China as a national trait.

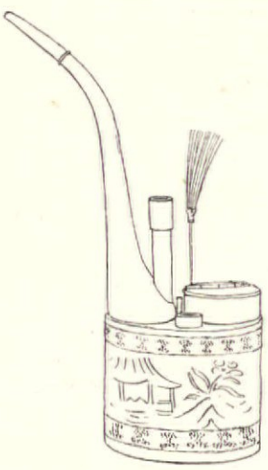
During my brief visit to this place it was plainly evident that I was *non personâ grata* and the intrusion would never have been made had any one given me the slightest premonition of the possible character of my reception, so my frankness of comment cannot be considered a breach of hospitality; there was no hospitality to breach.

I am not criticising the Chinese for this attitude, for it is about the only evidence of manhood from the standpoint of a Christian nation that they possess. It is too much to expect of a man that he should treat with more than cold reserve an individual who belongs to an alien race that has systematically robbed his people, filled his land with emissaries who have done their best to break down every sacred belief and cherished superstition, and that has defrauded his nation of vast tracts of territory and of enormous money indemnities.

I left the place by a narrow alley bordered by high walls of brick. The top of the walls had great rounded curves like the gable-ends of the Shanghai houses; these were imbricated with roofing-tiles, and just below the edge was a line of glazed panels having designs in high-relief. The water-conductors in the form of huge bamboo were made of cement, the joints and buds being well represented, the upper portion bulging out with flowers modelled in stucco and having no relation botanically with the bamboo. It is such incongruities in present Chinese art that jars upon the eye. It is possible, however, that some sentiment was to be conveyed by these flowers. The whole structure was an interesting illustration of the survival of form when the material of the device or the method of construction has been changed. This example was, of course, an obvious case, as bamboos are still used everywhere in the East as water-conductors.

. . . . . .

The Chinese are inveterate smokers of tobacco as well as snuff-takers. The tobacco is milder than ours and is cut in the finest threads. Among the wealthier classes a form of water-pipe made entirely of metal is used. These are often very elaborate and highly ornamented. The Salem Museum has a number of these pipes, and the accompanying sketch is a figure of one of them.

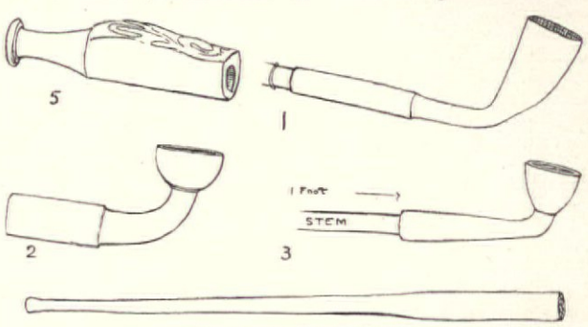


Tobacco Pipe with Water Receptacle.

A common form of pipe among the poorer classes consists of a metal bowl with short stem combined. Into this a wooden stem is fitted and on the other end a mouth-piece is secured. The mouth-piece is usually of metal, though bone, horn or jade may be used. The wooden stem may be 6 inches or 3 feet in length; when the stem is short it is often wound with tinsel or brass wire. The pipe-bowl may be a rough casting of brass or very thin white metal, the method of making being somewhat puzzling.

In Foo-Chow, according to Miss Gordon Cummings, the poorer classes use pipes in the form of large globular bowls of porcelain which are gaudily decorated. The thick wooden stem is 3 feet long and is used as a cane as well. These people use a coarse tobacco for their own use. The accompanying figures illustrate some of the pipe-bowls and mouth-pieces.

The Koreans use a similar form of pipe with long reed stems, and these are variously ornamented with curious designs burned on the surface. A fine collection of these Korean pipe-stems may be seen in the Museum in Salem.

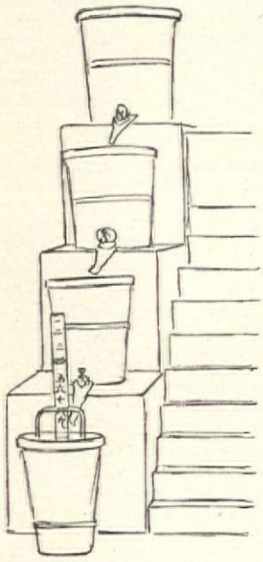


Figs. 1, 2, 3. Metallic Pipes.
Fig. 4. Metallic Mouthpiece.
Fig. 5. Jade Mouthpiece.

. . . . . .

The doorways seen on the street were in many cases very high, evidently to give ample room for the palanquins to enter. The doors are elaborately panelled and were double, and each door had two folds and these were hinged together. The door itself, instead of being hinged to the frame, was provided with a pivot above and below and close to the frame; these were held in appropriate sockets, the upper one being in the form of a carved embossment on the frame, the lower socket being made in the sill. This device is very ancient and may be found in the earliest Egyptian, Greek and Roman structures.

In my interesting wanderings about Canton my guide led me to the famous water-clock. It was a high building which looked as old as the clock, which was said to have been running for 400 years. The water-clock consisted of four deep copper vessels arranged on steps one above the other. A flight of short steps was at the side of this contrivance to enable the attendant to fill the upper bucket with water, and this has to be done twice in 24 hours. The water slowly drips through a faucet in the upper bucket to the next in turn, and so on down to the lowest one. In this is a float to which is attached an upright strip of wood having painted upon it the characters for one, two, three, and so on. This strip passes through a bail which spans the bucket, and as the float rises the numbers pass in succession through the bail and thus the hours of the day are rudely indicated. The keeper has a set of large boards upon which numbers are painted in black, and as each hour is indicated by the float the keeper hangs out a board with the corresponding number, and this may be seen only by those who are in a line with it down a rather wide avenue. Here the number remains in sight till the next hour is indicated by the float; in the meantime, unless one has closely followed up these sign-boards, there is no way of determining whether the time is one minute past nine, for example, or one minute to ten. To know the time within an hour seems to be quite enough for these peculiar people. I did not learn that a gong was beaten or a trumpet blown or a bell struck to announce the hours. Nothing, it seemed to me, could better illustrate the stolid and disastrous conservatism, the mental apathy, or, better, the atrophy of all adaptive and inventive faculty, in the nation, than this crude and primitive device. Thousands of Chinese have been abroad and while abroad have all had watches and clocks; in the poorest laundry place in America a clock hangs on the wall; in the Chinese theatre in San Francisco, a large Connecticut clock is hung against the wall over the stage in full view of the audience, and yet, here in Canton, a wealthy city of a million of inhabitants, the hours of the day have been rudely indicated by this ridiculous device for 400 years with only a small number of this vast population getting the benefit of it. EDWARD S. MORSE.



Water Clock, Canton.

[To be continued.]

NEW JERSEY ARCHITECTS' LICENSE LAW.

AN Act to regulate the Practice of Architecture.

Be it enacted *by the Senate and General Assembly of the State of New Jersey:* —

1. *Board of Architects.* — Within sixty days after the passage of this Act the Governor of the State of New Jersey shall appoint five persons, at least four of whom shall be, at the time of this appointment, architects residing in the State of New Jersey, and who have been engaged in the practice of their profession for at least ten years; the said five persons shall constitute the New Jersey State Board of Architects, two of whom shall be appointed to hold office for one year and three of whom shall be appointed to hold office two years.

2. *Succession of Board.* — Upon the expiration of the term of each member, the Governor shall appoint his successor for a term of two years, in like manner as the previous appointments; each member shall hold over after the expiration of his term until his successor shall have been duly appointed and qualified.

3. *Vacancies; Compensation.* — Any vacancy occurring in the membership of the State Board of Architects shall be filled for the balance of the unexpired term in like manner; the members of the Board shall serve without compensation for their services, except as hereinafter provided.

4. *Organization; Oath.* — The members of the New Jersey State Board of Architects shall, before entering upon the discharge of their duties, and within thirty days after their appointment, take and subscribe an oath before any officer authorized to administer oaths in the State, for the faithful performance of duty, and file the same with the Secretary of State; they shall annually elect from their number a President and a Secretary, who shall also be Treasurer, each of whom shall hold office for one year and until their successors shall have been duly elected and qualified; the Secretary and Treasurer shall receive such compensation for his services as may be determined by the Board.

5. *Rules, Records, etc.* — The Board may adopt all necessary rules, regulations and by-laws to govern its proceedings, not inconsistent with the laws of this State or of the United States; the Board may adopt a seal, and the Secretary shall have the care and custody thereof, and shall keep a record of all the proceedings of the Board, which shall be open to public examination.

6. *Quorum.* — Three members of the Board shall constitute a quorum.

7. *Special Meetings; Examinations.* — Special meetings of the Board shall be called by the Secretary upon the request of any two members by giving at least five days' written notice of the meeting to each member; the New Jersey State Board of Architects may adopt rules and regulations for the examination and registration of applicants desiring to practise architecture in accordance with the provisions of this Act, and may amend, modify and repeal such regulations from time to time.

8. *Public Notice of Changes.* — The Board shall immediately upon the election of each officer thereof, and upon the adoption, repeal or modification of the rules and regulations for the registration of applicants, file with the Secretary of State and publish in at least one daily newspaper in the State, the name and post-office address of each officer, and a copy of such rules and regulations or the amendment, repeal or modification thereof.

9. *Semi-Annual Examinations; Applicants.* — Provision shall be made by the State Board of Architects for holding examinations at least twice a year of applicants for registration to practise architecture, if there shall be any such applicants; any person over twenty-one years of age, upon payment of a fee of $5.00 to the Board, shall be entitled to enter any examination to determine the qualification for such registration.

10. *Who may be licensed.* — If the examination of any applicant for registration shall be satisfactory to the majority of the Board, and upon the payment of an additional fee of $15 to the said Board, a certificate shall be issued to the applicant, authorizing him to practise the profession of architecture; any person who shall at the time of the passage of this Act be engaged in the practice of architecture in this State, and who shall present to the State Board an affidavit to that effect, or a certificate from a similarly constituted Board of another State, and any person who is a member of the American Institute of Architects, shall be entitled to receive such certificate, upon the payment to the said Board of a regular fee of $5.00; each person licensed shall cause such license to be recorded in the Secretary of State's office.

11. *Revocation of License.* — Any certificate granted by the said Board or obtained by affidavit, as above provided, may be revoked by the said Board of Architects, for gross ignorance, recklessness, incompetency, dishonest practices, or other good and sufficient reasons: but before any certificate shall be revoked, the holder shall be entitled to at least twenty days' notice of the charge against him, and of the time and place, within the county of his residence, of the meeting of the Board, for the hearing and determination of such charge; for such purpose the Board shall have the powers of a court of record, sitting in the county in which its meeting shall be held, to issue subpœnas, and to compel the attendance and testimony of witnesses; witnesses shall be entitled to the same fee as a witness is allowed in the Circuit Courts of this State, to be paid in like manner; the accused shall be entitled to the subpœna of the Board for his witnesses, and a reasonable opportunity to produce his witnesses, and to be heard in person, or by counsel, in open public trial; the members of the Board shall have power to administer oaths and conduct such examination of witnesses under oath; and no certificate shall be revoked, except upon the unanimous vote of all the members of the Board; and any such revocation of certificates shall be certified in writing by the said State Board of Architects, under the hand of its President, or its President for the time being, and attested by the Secretary, with the official seal of said Board affixed thereto, and such certificate shall be filed in the office of the Secretary of State, who shall be paid the usual fee for filing similar documents in his office.

12. *Certified Copy in Evidence.* — A copy of any certificate granted by the said Board, or any revocation of the same, as by this Act provided, certified by the Secretary of State where the original certificate or revocation thereof is required to be filed by the provisions of this Act, to be a true copy of the original filed in his office under the hand and seal of the said Secretary of State, shall be competent and plenary evidence to prove the facts contained in the said certificate, to the same extent as if the original document had been produced and proved in any court of civil or criminal jurisdiction whatsoever.

Refusal of Certificate reviewable by Court. — Any person whose certificate shall be refused or revoked by said State Board shall have the right to appeal by *certiorari* to the Supreme Court for a review of such action, and the Supreme Court is hereby authorized and empowered to review and correct the action of said State Board, and the State Board shall forthwith carry out the judgment of the Supreme Court on such review.

13. *Penalty for practising without License.* — If any person shall pursue the practice of architecture in the State, or shall engage in this State in the business of preparing plans, specifications and preliminary data for the erection or alterations of buildings, or shall advertise or put out any sign, card or drawing, designating himself as an architect, having an office and doing business within this State without a certificate thereof, in accordance with the provisions of this Act, he shall be guilty of a misdemeanor, and upon conviction shall be fined not less than $50 and not more than $500 for each offence, or imprisonment in the county jail for a period of not less than one month.

14. *Exceptions.* — But nothing herein contained shall be construed to prohibit students or employés of licensed architects from

acting upon the authority of such licensed architects, or to prohibit any person in this State from acting as designer of any building that is to be constructed by himself or his employés, or to prevent any person from employing another person to prepare plans and specifications for the erection of any building with the full knowledge upon the part of said owner that said person is not a regularly registered architect according to the provisions of this Act.

15. *Expense of Board.* — The expense of said Board, and of the officers thereof, and of the examinations held by said Board, and of any other matter in connection with the provisions of this Act, shall be paid from the registration-fees above provided for, and not otherwise; and in no case shall any of such expense be paid by the State of New Jersey or be a charge against the said State.

16. *Annual Report.* — An itemized account of all receipts and expenditures of the said Board shall be kept by its Secretary, and a detailed report thereof, each year ending with the thirtieth day of September, duly verified by the affidavit of the said Secretary, shall be filed with the Secretary of the State within sixty days thereafter; the said Secretary of State to be paid such fees therefor as are now paid for filing similar papers in his office.

17. *Expenses met.* — The members of the Board shall be entitled to reimbursement for their travelling and hotel expenses, incurred in pursuance of their duties, not to exceed $5.00 per diem for each member of the said Board; the Secretary and Treasurer of the State Board of Architects shall receive such annual compensation as shall be provided by the Board, by resolution adopted by it at a regular meeting; no member of the Board shall be held personally responsible for any portion of the Secretary and Treasurer's salary, should the fees for certificates received by said Board be insufficient to meet the same.

18. *Disposition of Surplus.* — Any surplus of fees remaining in the Treasury after the payment of the expenses of the members of the Board, and the salary of Secretary and Treasurer, as herein provided for, shall be paid annually to the Treasurer of the State of New Jersey and shall only be paid out upon the warrant and authority thereafter of the Comptroller of the State.

Approved March 24, 1902.

RULES OF THE NEW JERSEY STATE BOARD OF ARCHITECTS.

RULES.

1. Roberts's Rules of Order shall govern the conduct of business at the meetings of the Board.

OFFICERS.

2. The State Board of Architects shall annually elect from its number a President and a Secretary, who shall also be Treasurer.

Said officers shall hold office until their successors shall have been duly elected and qualified.

The Secretary shall keep a record of all the Proceedings of the Board, which shall be open to public examination.

HEADQUARTERS.

3. The headquarters of the Board and the office of the Secretary and Treasurer shall be at 1 Exchange Place, Jersey City, N. J.

FINANCE.

4. All funds collected shall be deposited in bank to the credit of the Board, and all checks shall be signed by the Secretary and Treasurer and countersigned by the President, and no disbursements shall be made except on order of the Board. There shall be an Auditing Committee composed of the three members of the Board other than the President and the Secretary and Treasurer, who shall audit the Treasurer's accounts at least semi-annually. All bids shall be presented to the Board at a regular meeting.

MEETINGS.

5. The regular meetings of the Board shall be held at its headquarters on the third Friday of each month at 3 P. M., unless the time and place shall be otherwise ordered by the President. Special meetings of the Board shall be called by the Secretary upon the request of any two members by giving at least five days' written notice of the meeting to each member. Three members of the Board shall constitute a quorum.

EXAMINATIONS AND CERTIFICATES.

6. Any person over twenty-one years of age, upon the payment of a fee of Five ($5.00) Dollars to the Board shall be entitled to enter any examination to determine his or her qualifications for such registration. If the examination of any applicant for registration shall be satisfactory to the majority of the Board, and upon the payment of an additional fee of Fifteen ($15) Dollars to the said Board, a certificate shall be issued to the applicant authorizing him or her to practise the profession of architecture. Any person who shall at the time of the passage of this Act be engaged in the practice of architecture in this State, and who shall present to the said Board an affidavit to that effect, or a certificate from a similarly constituted Board of another State, and any person who is a member of the American Institute of Architects, shall be entitled to receive such certificate upon the payment to the said Board of Five ($5.00) Dollars.

Each person licensed shall cause such license to be recorded in the Secretary of State's office.

The examination of applicants for the practice of architecture shall be conducted by the Board, who shall publish a programme for examinations for certificates and for all other matters connected therewith.

The Board shall issue certificates to architects entitled to receive them as provided for in Sections 9 and 10 of the Act to regulate the Practice of Architecture as approved March 24, 1902. In all cases where an applicant for a certificate to practise architecture in the State of New Jersey shall cite to the Board existing buildings erected from his or her design and under his or her supervision, and when the character of such work and the applicant's connection therewith are such as to satisfy the Board of the applicant's ability to practise architecture, said demonstration shall take the place of written or oral examination. In carrying out this rule the Board shall require the personal attendance of the applicant when said applicant is a resident of the State of New Jersey. Applications for certificates from residents of other States may be considered at any meeting of the Board without the personal appearance of the applicant. If the proofs submitted in connection with said applications from resident and non-resident architects establish an ability equal to that demanded by the regular written and oral examinations, the Board may issue its certificate to the applicant.

Regular written and oral examinations shall be held as provided by the Act of March 24, 1902. The time shall be devoted to ascertaining the ability of the candidate to make practical application of his or her knowledge in the professional work of an architect. The examination shall be directed toward ascertaining the qualifications of the applicant in draughtsmanship, rendering, construction, design and the art of planning.

A diploma of graduation from the full course in architecture in any university or technical school approved by the Board may be accepted as satisfactory evidence of a competent knowledge of architectural design and construction, and shall entitle the recipient to a certificate to practise as an architect in the State of New Jersey, providing said applicant shall present evidence satisfactory to the Board that he or she has acquired the ability to successfully apply his or her knowledge to the designing construction and supervision of buildings, and shall have paid the fees of Five ($5.00) Dollars for admission to examination and the additional fee of Fifteen ($15) Dollars for certificate as prescribed by the Act.

Application for examination will be received at any time and should their number and urgency make it seem expedient to the Board to hold examinations at any time other than heretofore mentioned, due notice of such additional examinations will be forwarded by the Secretary to those whose applications are already filed at his office. Applications to enter a semi-annual examination should be at the Secretary's office one week before the time set for said examination.

Each member of a firm of practising architects must have a separate certificate. All certificates shall be signed by the President and Secretary.

SEAL.

7. The Board shall adopt a seal for its own use and shall have the words "New Jersey State Board of Architects" inscribed thereon, and the Secretary shall have the care and custody thereof.

Every registered architect *should* have a seal, the impression of which should contain the name of the architect, his place of business and the words "Registered Architect," with which all plans prepared by him should be stamped. Seals should be circular and 2 inches in diameter. The words "State of New Jersey" should appear at the top, the words "Registered Architect" at the bottom, the name and place of business in the centre. Where there is a co-partnership of architects the different names of the several members may appear on one seal. A seal should be used and not a rubber stamp.

CHARLES P. BALDWIN, Newark, *President;* HUGH ROBERTS, Jersey City, *Secretary and Treasurer;* ARNOLD H. MOSES, Camden; CHARLES EDWARDS, Paterson; DAVID B. PROVOOST, Elizabeth.

ILLUSTRATIONS

[*Contributors of drawings are requested to send also plans and a full and adequate description of the buildings, including a statement of cost.*]

THE NATIONAL BANK OF COMMERCE BUILDING, ST. LOUIS, MO. MR. ISAAC S. TAYLOR, ARCHITECT, ST. LOUIS, MO.

THE new National Bank of Commerce Building, located on southeast corner of Broadway and Olive St., is an office-building and bank combined, covering an area of 90′ x 187′, and cost, completed, $1,000,000. The exterior is built of Somes Sound, Me., granite, except cornice, which is of terra-cotta, to match the color of granite. The principal innovation introduced in this building is the fourteen marble columns in the bank-building. These were turned from the solid marble, then cored and slipped over the steel supports before second-story framing was installed.

COMMUNICATIONS

[*The editors cannot pay attention to demands of correspondents who forget to give their names and addresses as guaranty of good faith; nor do they hold themselves responsible for opinions expressed by their correspondents.*]

THE INSURANCE ENGINEERING EXPERIMENT-STATION.

BOSTON, MASS., June 3, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT:—

Dear Sirs, — In rejoinder to your editorial of May 31st on the Insurance Engineering Experiment-Station, please state that any architect, insurance-man, owner or other person who is interested in this undertaking may consider himself insured for $100,000 whether he holds such policies or not. He may then make a voluntary assessment upon himself of one cent per $100, say $10, remit that to me and thus become entitled to all the reports which may be issued on the work done in the Experiment Station. He will take his chance, as all the contributors have done, on the work proving to be worth its cost.

If "architects understood much better than mill-engineers or insurance-men the departures from the standard construction which really constitute the greatest danger in modern steel-frame buildings," as you put it, nothing could be more conducive to the work which we have undertaken than to have them communicate their knowledge to us or to put any questions to us which they themselves have not yet been able to answer. The doubts about present methods of steel-construction and the durability of the buildings are at present nearly all hypothetical. If architects can point out the way for us or show us the place where any actual examination of the condition of steel structures is now possible, they will do us a great service. Permit me to express a doubt as to there being any real knowledge based on facts which can be proved, as to most of the problems which we have undertaken to solve. If examinations could be made into the condition of existing steel frames, it might not be necessary to wait ten years, more or less, for the development of our own experimental structures. But where is the owner who will permit the steel in a building controlled by him to be uncovered, and where is the owner who will permit any thorough examination of a building ten or fifteen years old to be made?

You refer to the "usual underwriter's scorn for architects," hoping that we may invite suggestions from them. I think you are in error in using that term. Mutual underwriters have a great deal of sympathy for architects who, knowing better, are forced by owners and contractors to plan bad and unsafe buildings. On the other hand, to the mutual underwriter the common instruction in architecture appears to be defective. I have yet to know or hear of a problem being submitted to students in architecture for the construction of a textile-factory, paper-mill, workshop or warehouse, under the condition that the plan, elevation and decoration shall be made subordinate to the motive of the building and that the æsthetic effect shall be gained without wide variation from the customary cost, and with no variation that will impair the effective use of the building for its purpose. When such a problem is submitted and worked out by students in their architectural course it may become safe to employ the professional architect in industrial work. There are many owners and promoters of mill-construction who would be eager to relieve their buildings of the dreary monotony and lack of æsthetic effect by which they are afflicted, but they cannot sacrifice the effective use of the buildings merely to promote architectural effect.

During my business experience I have dealt with one large mill in which the services of a professional architect were called for in order to give it a good æsthetic appearance. He put on a roof-story which cost $10,000 for alteration before it could be made safe and which was never well adapted to the necessary work. In another instance I myself called for a plan of a mill-tower, in order to give good effect to an otherwise rather bare structure. The plan given me, in spite of all the caution that I could submit, was one that would have made the tower cost more than the mill.

My understanding of what constitutes good architecture is that the first consideration shall be given to the motive and use of the building and that all exterior effect shall be subordinated and so worked out as to be consistent with the prime motive of those who are putting up the building. A fine elevation of a costly stone church covering in and screening a dangerous interior construction of wood may not be called a "whited sepulchre," but may surely be entitled a concrete form of "petrified religion screening a sham."

Yours very truly, EDWARD ATKINSON.

NOTES AND CLIPPINGS

VORONIKHIN, THE RUSSIAN ARCHITECT. — In 1800 the Emperor Paul conceived the idea of building a magnificent cathedral in the "Nevskii Prospect" of St. Petersburg, to be dedicated to "Our Lady of Kazan," and Voronikhin, who was then professor at the Academy of Arts, was appointed architect. In the following year the first stone was laid by the Emperor Alexander, and the edifice was completed and solemnly consecrated in September, 1811. Criticism has not been sparing of its remarks — some of them exceedingly captious — on this piece of architecture. For no other reason than because the principal façade is extended by a semicircular colonnade, it has been called a copy of St. Peter's at Rome on a reduced scale, whereas there is no one point of similarity between the two buildings in any other respect. To note but one or two trifling differences, the front of St. Peter's has no prostyle or portico, and the pediment is a mere sham, one of most insignificant proportions; the colonnades again are there neither on the same scale nor of the same order as the church itself, nor are they combined with it. Andrei Nikophorovitch Voronikhin, the architect, was born in 1760, among the peasantry of Count Alexander Stroganov, who having heard of his talent for drawing sent him in 1777 to Moscow in order to be properly educated as an artist, and he there received some instruction from Bazhenov and Kazakov, two eminent architects. He was then sent to travel with his patron's son, Count Paul Stroganov and after visiting the southern provinces of Russia, Germany and Switzerland, resided for some time at Paris, diligently profiting by the opportunities there afforded of pursuing his architectural studies. In 1790 he returned to St. Petersburg, where Stroganov's protection soon brought him into notice and obtained for him employment. — *The Architect.*

PENAL-CODE SECTION RELATIVE TO HOURS OF LABOR UNCONSTITUTIONAL. — Subdivision 1 of Section 384 of the Penal Code of the State of New York, making it a crime on the part of any person or corporation, "who, contracting with the State or a municipal corporation shall require more than 8 hours' work for a day's labor," has been declared unconstitutional by Judge Beattie of the Orange County Court. The Orange County Road Construction Company had secured from the State and the Board of Supervisors of Orange County a contract to improve and construct certain roads in that county, and had been indicted for requiring of its workmen more than 8 hours as a day's labor. Judge Beattie bases his decision on the case of People ex. rel. Rodgers *vs.* Coler (166 N. Y., 1), in which the Court of Appeals practically held the labor law to be unconstitutional. He says in part: "The obvious purpose of the labor law was to narrow as far as possible the field from which a supply of laborers could be obtained, by prohibiting directly the employment of aliens, and indirectly the employment of non-residents, and, having done this, to destroy, to the extent that the extra time represented actual value and labor, the benefit to be derived by contractors from work which might have been accomplished in 10 hours as distinguished from the work done by the same laborers within 8 hours. The whole effect of the legislation was to compel payment for time during which no labor was to be performed. The law fixed the length of the day, not with reference to the ability of a person to labor or with relation to the hours during which labor could not be properly or advantageously done. It did not undertake to strike at early hours or late hours, but arbitrarily fixed the length of the day, so that for a day's pay the employer should receive just so much less labor. If it is permissible to impose such burden upon the employer by fixing the length of a day at 8 hours, there is nothing to prevent a lessening of the time, so that at the dictation of some interest, a half-day's labor should be counted as a full day's work." — *N. Y. Times.*

WIND CAVE, SOUTH DAKOTA. — The Government has just finished making a survey of the famous Wind Cave, a remarkable freak of nature near Hot Springs, which is to be thrown open as a public park. Wind Cave was discovered some dozen years ago by a cowboy, a gushing wind blowing his hat some distance down the gulch. The following day returning with unbelieving friends, the discoverer found the current reversed and his hat was sucked in out of sight. The direction of the wind is governed by the barometer. There are 3,000 chambers, and over 90 miles of passage-ways have been explored and opened to the public. The area is more than 2 miles square. It is the intention of the Government to give the public free access to the cave, but it will never be visited without a guide. While there are well-trod trails, no one not familiar would dare venture far from the entrance. The trip through one of the three principal routes can be made in about 3 hours, the distance being 5 to 7 miles. The principal chambers have been named and dedicated by lodges, fraternal orders and denominations, so that nearly every person visiting the cave finds special attractions. — *Boston Transcript.*

PROFESSOR MERRIAM'S MONUMENT AT ATHENS. — The monument which the members of the Archæological Institute of America decided to erect over the grave of Professor Merriam at Athens has been completed. Professor Merriam was Professor of Greek Archæology and Epigraphy in Columbia University. His death occurred in January, 1895, in Athens, where he was on leave of absence. The monument was designed by Edward L. Tilton, the architect of the Argos excavations, who offered his services as a personal tribute to the memory of Professor Merriam. Funds for the monument were provided by William E. Dodge, Heber R. Bishop, Frederic J. De Peyster, S. P. Avery and ex-President Low. — *N. Y. Tribune.*

BLASTING WITH FREEZING WATER. — An interesting bit of quarrying was recently accomplished at Rubislaw quarries, Aberdeen, Scotland. A large stone had been drilled, ready for splitting, when the thought struck the foreman that the severe frost which prevailed might be utilized. Water was poured into each of the drill-holes, and it was found after a couple of days that the block of granite had completely burst open. An idea of the immense power of the frost will be gathered when it is stated that the stone thus detached measures 12′ x 5′, and has a weight of about six tons. — *Exchange.*

NOTES AND CLIPPINGS. 88

IT would take a very strong and nearly unanimous appeal from our subscribers to induce us to continue the form of publication which, during the current quarter, has been given experimentally to our International Edition. We are not satisfied with the practical working of the new method, which seemed to have the promise of many desirable possibilities in its favor, and believe that no mistake will be made in returning at the earliest practicable moment to the original form of publication. From the first issue for July, therefore, subscribers to the International Edition will again receive their copy in its familiar blue-covered weekly form.

THE New York Department of Buildings has been very active of late in examining hotels, and prescribing fire-escapes, and contracts are said to have been already made for the equipment of more than two hundred and fifty hotels. Among others, the Fifth Avenue Hotel is to have two new fire-escapes on the Madison Square front; the Holland House is to have one on Thirtieth Street, and the Waldorf-Astoria is to have two on the west wall. For the Hotel Imperial, a rather small building, constructed about fifteen years ago, and supposed to be perfectly fireproof, six new lines of fire-escapes have been ordered, two on Broadway, two on Thirty-first Street, and two on Thirty-second Street. The proprietors of the better class of hotels have shown a commendable willingness to comply with the directions of the Department, and hotel guests in New York will soon be able to sleep with confidence of security, at least against the dangers of fire. Whether the abundance of fire-escapes will bring any counterbalancing annoyances remains to be seen. Years ago, when the law was adopted in New York requiring a rope to be placed at the windows of every hotel bedroom, long enough to enable its occupant to climb down to the ground in case of fire, some of the hotel proprietors complained that their guests utilized the ropes to depart without paying their bills. The fire-escapes would be less available for this purpose than the ropes, but it is not impossible that they might, in hotels less carefully guarded than those on Fifth Avenue and Broadway, occasionally serve for the entrance or exit of thieves.

THE death of the lamented James Brown Lord, in New York, has given occasion for a discussion of much interest to contractors and owners. During Mr. Lord's illness, the owner of the adjoining estate undertook some blasting operations, which caused great annoyance to the neighborhood. The people who were in good health were able to move away while the annoyance lasted, but Mr. Lord could not be moved, and suffered greatly from the noise and nervous shocks incident to the blasting. Mr. Lord's family, unable to secure a temporary suspension of the operations, applied to the Federal Court, but obtained no relief, the Court holding that in such cases the only remedy of the sufferer lay in an appeal to the humanity of the offender. This seems to have been a slender reliance, for the blasting continued, and Mr. Lord's death is believed to have been hastened, if it was not caused, by his sufferings from it.

MR. RUSKIN once made a characteristic addition to the science of political economy by observing that "Food can only be got out of the ground, and happiness only out of honesty." What degree of happiness the promoters of "trusts" and "amalgamations" and "deals" are likely to find, in this world or elsewhere, we will not inquire, but it is worth remarking that the extraordinary fever of activity and speculation which we have witnessed for the last three years followed, in time, at least, if not in any relation of cause and effect, three years of enormous crops in the West. Politicians, naturally, attribute all prosperity to their own efforts; and the Republicans have not failed to point to the immense railway traffic, and the unparalleled consumption of iron in this country, as the results of the protective system for which they claim to be responsible; but the protective system has been established for thirty years, and was in full force at the time when Mr. Bryan was urging the Western farmers to fall upon the "money-lenders" of the East, and make up out of their pockets the deficits incident to agricultural operations; when one-third of all the railway mileage of the United States was operated by receivers in bankruptcy; when structural iron was sold here for less than one cent per pound, and when learned and ingenious articles appeared every day in the newspapers and magazines, proving that the wheat-growing capacity of the American soil was exhausted; that modern conditions had permanently reduced the possible return from railway traffic, and that overproduction had brought ruin upon American industries. Then followed three years of great harvests; Southwestern Kansas, which, owing to its dry climate, had the reputation of producing a crop only one year in five, and which its inhabitants were represented as being on the point of abandoning, had three enormous crops in succession; and the "exhausted" American soil proved more productive than ever, while the wheat crops of Argentina, Russia and India were deficient. It must be remembered that a single good crop on a Western farm often sells for a sum equal to the whole value of the farm; and the agriculturists who, a short time before, wanted to rob the Eastern capitalists who had lent them the money to buy their farms now paid off their mortgages, put cash in the nearest bank, and invested the surplus in such articles of luxury as pleased their fancy. The railroads soon felt the effect of having large crops to haul to the East, and pianos, bicycles and building materials to carry back again, and many of the lines recently bankrupt began to pay dividends. This condition of things has lasted until now, with the sinister addition, of late, of a speculation so wild that the trust companies of New York, for example, have, according to their own statement, only nine million dollars in cash among them with which to meet checks on nine hundred millions of deposits. Whether a reaction will come, and, if so, how soon it will arrive, and how violent it will be, are matters which no one, perhaps, can predict; but, although the railroad managers say, with undoubted truth, that the transportation of grain furnishes only a small part of their revenue, there is reason to believe that a much larger portion of their income is dependent upon the prosperity of the people who raise the grain, and that a year or two of severe drought, or of locusts, would produce the same effect that similar causes have produced so many times before.

THE *Builder* has some singular ideas about the United States, and not the least singular of these is one which we find in a recent issue, relating to statues. Speaking of the colossal statue of King Victor Emmanuel, now on the point of being cast in bronze for the adornment of his great monument in Rome, and comparing it with the figure of Saint Charles Borromeo, at Arona, on the Lake Maggiore, it says that "This statue may be, perhaps, — and it is to be hoped will be, — considered as the final attempt of the Italian sculptors in the 'colossal style'." It then informs its readers that in Italy, within the past few years, "many statues of this kind have been executed in marble and bronze for home consumption and for America." It would puzzle an American to say where these colossal statues have been put; but the *Builder* enlightens our darkness by saying that "A portrait statue of one of the Vanderbilts as a River God, many yards high, was commissioned in Florence for some American town fifteen years ago, — a sample of the American taste in such things

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

which culminates in the lighthouse of New York." We should be glad to know what American town is graced with a colossal statue, or any other kind of statue, of any member of the Vanderbilt family in the disguise of a River God. Americans are not, as a rule, inclined to invite public ridicule by foolish display, and a family less disposed to anything of the kind than the one in question it would be hard to find, in America or anywhere else.

AS for the New York "lighthouse," which the *Builder* regards as the "culmination" of the American bad taste which delights in colossal Vanderbilt River Gods, it may be well to observe that the New York statue of "Liberty," which, by the way, never has been of any use as a lighthouse, and now does not even have its torch lighted, although it is certainly colossal, is not a product of American taste, but was designed and executed in France, by a French sculptor, at the request of French admirers of the United States, for presentation to the city of New York. Moreover, instead of being the "culmination" of a series of American works of the sort, it is almost the only colossal statue in this country, with the exception of the figure of "Liberty" crowning the Capitol at Washington, and the William Penn on top of the tower of the Philadelphia City Building, neither of which pretend to any merit as sculpture; and it was regarded at the time as an introduction to this country of a form of art which has been popular in the Old World for at least seven thousand years. The *Builder* pays, unintentionally, a very pretty compliment to the Americans, when it sneers at them for sharing with the Greeks and Egyptians the taste in sculpture which produced the Olympian Zeus, and the Athena of the Acropolis, to say nothing of the multitudes of gigantic statues in Egypt. As a matter of fact, the fashion of erecting colossal statues, which the *Builder* lays to the Italians, prevails more in France than anywhere else, except, perhaps, of late years, in Germany. Bartholdi was chosen to carry out the New York statue of "Liberty," which we venture to consider a very beautiful and successful design, in part on account of the reputation that he had gained by his colossal statue of Vercingetorix, which stands on the hill of Alesia, near Dijon; and many other colossal figures exist in various parts of France as well as in Italy.

A VERY important trade-union case was decided in England a short time ago. One Read, a man twenty-five years old, made a contract of apprenticeship with Wigg & Wright, stone-masons, by which he was to work for them for three years, receiving fifteen shillings a week as wages during that time, and they were to teach him the trade of a stone-mason. Wigg & Wright, as well as all their journeymen, were members of the "Friendly Society of Operative Stone-masons." One of the rules of the Society, which Wigg & Wright, as employers, had agreed to, and signed, provided that no one over sixteen years of age, except masons' sons and step-sons, should be received as an apprentice. When Read had been working for Wigg & Wright nearly three months, the Society held a meeting, at which his case was taken up, and a resolution was passed, to the effect that if he did any work for the firm as a stone-mason, the Society should be immediately notified. In consequence of this action, Wigg & Wright kept Read employed only as a laborer, and did not give him any of the instruction in their trade that they had promised. Some nine months later, the Society, which seems to have been alarmed by Read's intelligence, notified Wigg & Wright that, if he was given any stone-mason's work to do, "prompt action" would be taken; this "prompt action" being, as the officials of the Society confessed, a strike at two hours' notice. Read then brought suit against the Society for damages, for having wrongfully and maliciously induced Wigg & Wright to break their contract with him. The lower Court found for the defendants, holding that they had acted in good faith, and from no improper motive, and that Read had no cause of action; but the King's Bench has now reversed the decision. The Court said that Read, by virtue of his contract, had a right to demand that Wigg & Wright should teach him their trade. The Society claimed that it had also a contract with Wigg & Wright, which was inconsistent with their contract with Read. The Court said that the existence of this contract was not sufficiently shown by the evidence; but supposing it to exist, if it was in restraint of trade, it was illegal, and incapable of enforcement, and the majority of the Court were of opinion that the case should be remanded for a new trial. The Lord Chief Justice, in a separate opinion, went farther than his colleagues, holding that judgment should have been ordered for the plaintiff. Supposing the contract between the Society and Wigg & Wright to have existed, the Society was at liberty, if it suffered any injury from its violation by Wigg & Wright, to claim damages from them. Instead of this, the officers of the Society, without pretending that the Society, or any of its members, was injured, or was likely to be injured, by the action of Wigg & Wright, unreasonably induced them to commit a wrong against Read.

WE do not know that Americans would be considered as having a right to criticise the plans of English architects; but the repairing of Pearson's beautiful Truro Cathedral is a matter of general professional interest. It seems that the bases of some of the piers in the building have cracked, and Sir Thomas Drew, who was called in to examine them, has made a report, illustrated with diagrams, setting forth very clearly the causes of the trouble, and making suggestions for remedying it. As shown in the diagrams, the foundations under the piers seem to be of coursed rubble, very poorly bonded, and so arranged that the outer stones run only about one-third their length under the pier, the other two-thirds projecting outside. The most elementary principles of construction, as taught to American students, point out that, with a foundation built in this way, the reaction of the ground tends to tilt upward the free end of the outer stones, dislocating the rubble-work below, and throwing the weight of the pier on a small surface of masonry under the middle portion of it. The diagram shows no attempt to prevent such dislocation by the bonding; on the contrary, the joints could hardly be arranged more favorably for it. The bases of the piers are made of two large flat stones, one above the other, one less than twelve inches thick, and the other less than ten inches; and we cannot consider it surprising that such stones, resting on a foundation of which the inner portion was settling under compression, while the outer part was being tilted upward with enormous force, should have broken. The Report suggests that the trouble may have been due to the bed of asphalt, half an inch thick, which was interposed, as a damp-course, between the base of the pier and the rubble foundation. It is true that a layer of asphalt, which is always more or less plastic, and would yield to any force tending to cause lateral movement of the foot of the pier, is an objectionable feature in such a construction, but we cannot see how it should have contributed to the fracture of the base-stones. On the contrary, it would be likely, by its plasticity, to delay for a short time the effect of the rolling of the outer foundation-stones.

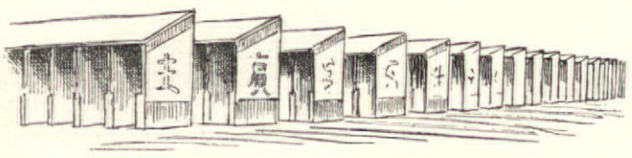
THE remedy suggested by Sir Thomas Drew for the trouble looks, at first sight, rather doubtful. According to the diagram given in the Report, he proposes to shore up the injured piers; remove the broken base-stones, replacing them with a single stone, instead of two thin ones; lower the rubble foundation, apparently by taking off the upper course, and replace this course by a layer of concrete, of the same thickness. If this layer of concrete were stiffened with a sufficient number of iron beams, as would be done in this country, the remedy would probably be effectual; but, as the concrete course is shown projecting, to a distance considerably more than twice its height, beyond the base of the pier, it would, without the embedded gridiron of beams, probably soon break off under the pier, at a little distance inside the face of the plinth, throwing the load, as before, on the middle portion of the foundation, and allowing the rubble blocks on the outside to roll as badly as ever.

CELLULOID is so much used now that it might be well to remember that it is a highly combustible, not to say explosive, substance. Not long ago, according to *Fire and Water*, a party of insurance officials were dining in honor of one of their number, and in the course of the after-dinner oratory, one of the speakers, to make room for the utterance of his eloquent periods, took his cigar out of his mouth, and laid it on the table. The lighted end of the cigar happened to come in contact with the celluloid handle of a dessert knife, and, in a moment, there was a bright flash, and the celluloid covering of the handle began to blaze. The fire was extinguished by plunging the handle of the knife into a finger-bowl, but the insurance-men present added a mental memorandum of the properties of celluloid as a fire-hazard to their stores of professional knowledge.

JOURNAL SKETCHES IN CHINA.[1]—VI.

CANTON.

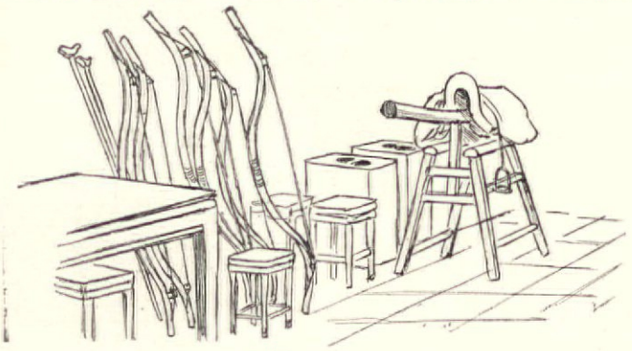
I WAS naturally curious to see the prison in Canton, having seen the one in Shanghai. That was so vile that, in the more refined city of Canton, I was led to believe that there might be some advance in prison management. If anything, it was even worse than the northern horror. The prisoners looked starved and were in the most ragged and most haggard condition. Many of them were loafing in the prison-yard; others were in low coops, hardly high enough to accommodate a dog; some had their heads thrust through square plank-like affairs, unable to reach their faces, over which flies crawled at will.



Examination Hall, Canton.

They could not, of course, feed themselves, but had to depend upon relatives or humane friends to perform this service. Nearby was a simple enclosure surrounded by high walls, known as the execution-grounds. At the time of my visit, the ground was covered with pottery in the form of little kitchen braziers; apparently some one had hired the place for the temporary storage of his pottery stock. Near the walls were larger jars, in which the heads of the executed were placed. Judging from the description of the Spanish prisons in Cuba, Porto Rico and the Philippines, Spain is the only European country which must be placed on a level with China in this respect.

The examination-hall, as it is called, though there was no trace of a hall on the grounds according to our meaning of the word, consisted of rows of long, narrow sheds running at right angles to a broad area which might be called a yard or avenue. These low sheds were divided by partitions open in front; if they had been furnished with doors they would have resembled the bathing-houses along our seaside resorts. These structures were built of brick, with brick partitions, and the individual cells were not over 4 feet wide. The number of them has been variously stated to be 7,500 and 10,000. The candidates who compete for examination come from all parts of the Empire. These include young men and old men, some of whom have reached the age of eighty or ninety years, who have been competing since they were boys and appear again and again to win the coveted prize of recognition and, if successful, to get some office under Government with a modest stipend, the balance of their salary being squeezed out of the inhabitants by fraud and persecution. Early in the morning a single text from Confucius or some other ancient classical writer is issued to all, each one receiving the same text. On this they are all to write an essay and deliver it the next morning. An ignoramus on everything but Chinese classics may beat other numbskulls in writing the best composition on the text given and attain some office dealing with matters pertaining to the nineteenth century. As an illustration, a competitor has secured a position in the army by passing a literary examination on the art of war, not as understood to-day, but with the art as set forth by authorities 3,000 years ago. One of these authorities, held in highest repute, Sun-Tse by name, solemnly recommends such a manœuvre as this: "Spread in the camp of the enemy voluptuous musical airs, so as to soften his heart." No wonder in the recent war with Japan, Chinese generals were found with singing-birds in cages and a retinue of concubines, while every soldier carried a fan and every third one a banner. How inferior the Japanese in these matters! Undaunted by the slurs of English writers, who have repeatedly stigmatized the Japanese as a nation of copyists, they sent their students to military academies abroad; their men graduated at our Naval Academy; then they established a naval college of their own, and to-day their army and navy, in effectiveness and morale, are fully abreast of the armies



Drill Room, Canton.

and navies of Europe and, according to an English military critic, superior to many of them.

The matter of literary examination for public office has been repeatedly dwelt upon, yet no one can realize the overpowering absurdity of it until he comes to examine the conditions minutely. China is supposed to have an army and navy, arsenals and departments of telegraph, customs, etc. Now, let one open a page of Confucius, the "Doctrine of the Mean," or "Analects," for example, or any ancient classic, and find if he can a single line which would enable him to perform any of the duties involved in the above departments. Everywhere he would find admonitions to be just, good and honest. References to an honest judge and upright ruler, etc., frequently occur in these venerable pages, but of telegraphy, railroads, customs or anything else pertaining to nineteenth-century civilization not a word. He has evidently taken these moral admonitions in the usual Chinese reverse sense, for outside of the municipal affairs of New York and Philadelphia no greater corruption or dishonesty exists than can be found in China. Despite the fact that their armies have been repeatedly beaten by small bodies of European soldiers and, within recent years, suffered an ignominious and crushing defeat at the hands of Japan, in each case paying enormous indemnities, the Chinese still go through these antiquated examinations in order to secure positions in these modern departments. The appointments in the British Army are nearly as absurd as the Chinese practice, though based on a different method.
